

MINIMUM MODELS OF SECOND-ORDER SET THEORIES

KAMERYN J. WILLIAMS

ABSTRACT. In this article I investigate the phenomenon of minimum models of second-order set theories, focusing on Kelley–Morse set theory KM, Gödel–Bernays set theory GB, and GB augmented with the principle of Elementary Transfinite Recursion. The main results are the following. (1) A countable model of ZFC has a minimum GBC-realization if and only if it admits a parametrically definable global well-order. (2) Countable models of GBC admit minimal extensions with the same sets. (3) There is no minimum transitive model of KM. (4) There is a minimum β -model of GB + ETR. The main question left unanswered by this article is whether there is a minimum transitive model of GB + ETR.

1. INTRODUCTION

The jumping-off point for this article is the following well-known theorem.

Theorem (Shepherdson [She53], Cohen [Coh63]). *If there is a transitive model of ZF then there is a minimum transitive model of ZF. That is, there is a transitive model M of ZF so that if N is any transitive model of ZF then $M \subseteq N$. Indeed, this minimum model also satisfies AC and $V = L$.*

From a modern perspective, this result is not difficult to prove. This minimum model is L_α where α is the least height of a transitive model of ZF. The absoluteness of L gives that L_α is contained in every transitive model of ZF.¹

This proof can be generalized to get analogous results for many weakenings or strengthenings T of ZF. What we need from T is that it has a transitive model, is strong enough to build the inner model L , and is absolute to L , meaning that $M \models T$ implies $L^M \models T$. On the weaker side, KP satisfies the conditions—see [Bar75, chapter II]. The minimum transitive model of KP is $L_\omega = V_\omega$ and the minimum transitive model of KP + Infinity is $L_{\omega_1^{\text{CK}}}$, where ω_1^{CK} is the Church–Kleene ordinal. On the stronger side, we get minimum transitive models of ZFC plus small large cardinals.

Key words and phrases. Kelley–Morse, Gödel–Bernays, elementary transfinite recursion, minimum model, second-order set theory.

I am grateful to the anonymous referee for their many helpful comments. The present article is substantially improved thanks to their time and care in reviewing it. I also want to thank Joel David Hamkins, under whose supervision I wrote my dissertation, written while this paper was under review and consisting in part of the material herein.

¹The anonymous referee noted that the Shepherdson–Cohen minimum model L_α is also the minimum model of ZF in the following sense: it is, up to isomorphism, the unique model of ZF which can be isomorphically embedded into every model of ZF. I reproduce their proof of this fact here. If N is well-founded, then by the Shepherdson–Cohen theorem L_α embeds into a transitive submodel of N . In this case, the embedding is moreover Δ_0 -elementary. If N is not well-founded, it has a countable elementary submodel N_0 which must also be ill-founded. By a theorem of Hamkins [Ham13, corollary 29] there is therefore an embedding of L_α into N_0 , hence an embedding of L_α into N . That L_α is the unique such model follows from the Shepherdson–Cohen theorem combined with the fact that any model which embeds into a well-founded model must also well-founded.

There is, for instance, a minimum transitive model of $\text{ZFC} + \text{there is a Mahlo cardinal}$. It is not difficult to see, however, that this cannot be extended too far up the large cardinal hierarchy.

There is no minimum transitive model of any T extending ZFC which proves there is a measurable cardinal. This is because by a well-known theorem of Scott [Sco61], if $N \models \text{ZFC}$ has a measurable cardinal then there is an elementary embedding $j : N \rightarrow M$ to an inner model M , with the measure not in M .² So any transitive model of such T contains a strictly smaller transitive model of T .

Moreover observe that Scott's theorem can be internalized to any model of ZFC with a measurable cardinal, whether or not it is well-founded. This yields that any $M \models \text{ZFC} + \text{"there is measurable cardinal"}$ has a proper transitive submodel which satisfies the same first-order theory. Define the pre-order $\triangleleft_{\text{end}}$ on models of ZFC as $M \triangleleft_{\text{end}} N$ if M embeds as a transitive submodel of N . Or to use language that will be introduced in the next section, $M \triangleleft_{\text{end}} N$ if and only if N *end-extends* an isomorphic copy of M . So this same argument shows that if T is any extension of ZFC which proves there is a measurable cardinal, then there is no $\triangleleft_{\text{end}}$ -minimal model of T .³

In contrast, results from inner model theory show that if there is a transitive model which thinks the ordinal κ is measurable, then there is a minimum such model. This extends to strong cardinals, Woodin cardinals, etc.⁴

A second direction the Shepherdson–Cohen result could be generalized is from first-order set theory to second-order set theory. Given some second-order set theory, does it have a minimum transitive model? A natural first theory to look at here is GB , Gödel–Bernays set theory. This was already answered by Shepherdson in the positive; see theorem 19.

While the existence of a minimum transitive model of GB is already settled, I also look the situation where we fix the sets of our model but allow the classes to vary. In this context, it is most interesting to consider GBC , Gödel–Bernays set theory with Global Choice.

Main Theorem 1. *A countable model $M \models \text{ZFC}$ has a minimum GBC -realization if and only if M has a parametrically definable global well-ordering.*

Main Theorem 2. *If $(M, \mathcal{X}) \models \text{GBC}$ is countable, then $\{\mathcal{Y} : (M, \mathcal{Y}) \models \text{GBC} \text{ and } \mathcal{X} \subsetneq \mathcal{Y}\}$ has minimal elements.*

In contrast to the Shepherdson result, stronger second-order set theories lack minimum transitive models.

Main Theorem 3. *There is no minimum transitive model of KM . Nor is there a minimum transitive model of $\text{GB} + \Pi_1^1\text{-CA}$, nor any computably axiomatizable extension thereof.*

I also consider theories intermediate between GB and $\text{GB} + \Pi_1^1\text{-CA}$. The most important such theory I will consider is $\text{GB} + \text{ETR}$, where ETR is the principle of Elementary Transfinite Recursion. And I consider other theories obtained by weakening ETR . My main result here concerns β -models of $\text{GB} + \text{ETR}$. A transitive model of second-order set theory is a β -model if it is correct about well-foundedness for class relations. This gives a more restricted class of models.

²For a full proof, consult [Jec03, Lemma 17.9 (ii)].

³I thank the referee for pointing out this extension of the argument.

⁴Briefly: It is well-known that if κ is measurable there is a minimum inner model which thinks κ is measurable, of the form $L[U]$ where U is a normal measure on κ . See [Kan04, section 20] for a proof. From this it follows that if α is the least height of a model of ZFC which thinks κ is measurable then a model of the form $L_\alpha[U]$ is the minimum transitive model which thinks that κ is measurable. A similar argument can be made for other large cardinals with canonical inner models. The reader is advised to consult [Zem01] for the construction up to a strong cardinal, and [MS94] for the argument for Woodin cardinals.

Main Theorem 4. *There is a minimum β -model of $\text{GB} + \text{ETR}$, if there is any β -model of $\text{GB} + \text{ETR}$.*

Combined with the results that GB and KM have minimum β -models, due respectively to Shepherdson [She53] and Marek and Mostowski [MM75],⁵ we have the following state of affairs.

	minimum transitive model?	minimum β -model?
GB	Y	Y
$\text{GB} + \text{ETR}$?	Y
KM	N	Y

Left open by this article is filling in the question mark in the table: does $\text{GB} + \text{ETR}$ have a minimum transitive model? While I do not answer this question, I do show that weak enough fragments of $\text{GB} + \text{ETR}$ do have minimum transitive models; in particular, $\text{GB} + \text{ETR}_{\text{Ord}}$ has a minimum transitive model.⁶

The structure of this article is as follows. I first discuss some preliminary definitions and results, followed by a look at some antecedents for my work in the literature, and parallels to work in second-order arithmetic. The remainder of the paper is organized by the strength of the theories considered. These three sections are largely independent, and may be read by the reader in any order. First comes the section about GB . I present proofs of the above-mentioned Shepherdson results and prove main theorems 1 and 2. The next section is devoted to ETR and its fragments. I prove main theorem 4 and show that there are minimum transitive models for GB plus weak enough fragments of ETR . I end the section by separating these fragments of ETR . The final section of the paper is about KM and other strong second-order set theories. I prove main theorem 3 and give a proof of the Marek–Mostowski result that there is a minimum β -model of KM . I also show that no countable transitive model of ZF has a minimum KM -realization.

2. PRELIMINARIES

The second-order set theories considered in this article are formulated so that their models consist of two sorts, the *sets* of or *first-order part* of the model and the *classes* of or *second-order part* of the model. All second-order set theories considered in this paper will include an axiom asserting that extensionality holds for classes. This ensures that any model of these theories is isomorphic to one whose second-order part consists of subsets of the first-order part. Without loss we can consider only such models. Formally, models of second-order set theories are of the form $(M, \mathcal{X}; \in^{(M, \mathcal{X})})$ where M is the first-order part, \mathcal{X} is the second-order part, $\in^{(M, \mathcal{X})}$ is the membership relation for the model between sets and sets or between sets and classes. For simplicity, I will write (M, \mathcal{X}) , suppressing writing the membership relation. I will use \in^M , or simply \in if it is unambiguous, to refer to the membership relation of M . In general, when talking about a multi-sorted structure I will separate the sorts and the relations, functions, and constants with a semicolon.

A model (M, \mathcal{X}) of second-order set theory is *transitive* if M and \mathcal{X} are transitive and its membership relation is the true \in . By the convention that \mathcal{X} consists of subsets of M , for the theories considered in this article it is enough just to ask for M itself to be transitive.

Definition 5. Given a second-order set theory T , the *minimum transitive model* of T , provided it exists, is a transitive model (M, \mathcal{X}) of T so that if (N, \mathcal{Y}) is any transitive model of T then $M \subseteq N$ and $\mathcal{X} \subseteq \mathcal{Y}$. For the theories we consider, this is equivalent to requiring that $\mathcal{X} \subseteq \mathcal{Y}$.

⁵See, respectively, corollary 20 and theorem 46.

⁶ ETR_{Ord} is the restriction of ETR to recursions along Ord . See definition 9.

If M is a first-order model of set theory and T is a second-order set theory, say that $\mathcal{X} \subseteq \mathcal{P}(M)$ is a T -realization for M if $(M, \mathcal{X}) \models T$. If there is some T -realization for M then we say that M is T -realizable. The *minimum T -realization for M* , provided it exists, is $\mathcal{X} \subseteq \mathcal{P}(M)$ so that $(M, \mathcal{X}) \models T$ and for any $\mathcal{Y} \subseteq \mathcal{P}(M)$ if $(M, \mathcal{Y}) \models T$ then $\mathcal{X} \subseteq \mathcal{Y}$. That is, \mathcal{X} is the minimum T -realization for M if it is the minimum element in the poset consisting of all T -realizations for M ordered by the subset relation.

We can also talk about minimal T -realizations, minimal transitive models of T , and so forth. Recall the distinction between minimal and minimum elements. Given a partial order $(P, <)$, a *minimal* element m is one so that there is no $p < m$ in P . A *minimum* element m has the stronger property that $m \leq p$ for all $p \in P$. So, for example, a minimal transitive model of ZF is one which does not contain any strictly smaller transitive model, while the minimum transitive model of ZF is contained inside all transitive models.⁷

Observe that if \mathcal{X} is the minimum T -realization for M , then $\mathcal{X} = \bigcap \{\mathcal{Y} : (M, \mathcal{Y}) \models T\}$. This is the motivation for the following definition.

Definition 6. Let T be a second-order set theory and let M be a model of ZF. Set

$$\mathcal{X}_T(M) = \bigcap \{\mathcal{Y} : (M, \mathcal{Y}) \models T\}.$$

If the context is clear I will just write \mathcal{X}_T .

We can then phrase the question of whether M has a minimum T -realization as: is it the case that $(M, \mathcal{X}_T) \models T$? In case the answer is no, the question is then: what axioms are satisfied by (M, \mathcal{X}_T) ?

A transitive model (M, \mathcal{X}) of second-order set theory is a β -model if it is correct about well-foundedness for class relations. That is, if $R \in \mathcal{X}$ and $(M, \mathcal{X}) \models$ “ R is well-founded” then R really is well-founded. Not every transitive model is a β -model, even if we restrict to models satisfying a strong second-order set theory. This is in contrast to the well-known fact that well-foundedness is absolute for transitive models of ZFC. For models of ZFC, there are two characterizations of well-foundedness: a Π_1 characterization, namely that every nonempty subset of $\text{dom } R$ has an R -minimal element; and a Σ_1 characterization, namely there is a ranking function from R to Ord .

In the second-order context, we still have access to the Π_1^0 characterization.⁸ The theories we consider will prove that a class relation R has that every nonempty subclass of its domain has a minimal element if and only if every nonempty subset of its domain has a minimal element.⁹ So in fact it takes only a single unbounded first-order universal quantifier to assert that R is well-founded.

As such, well-foundedness is downward absolute to transitive models of second-order set theory; if $R \in \mathcal{X}$ is well-founded in V then (M, \mathcal{X}) thinks R is well-founded. However, well-foundedness for class relations is not upward absolute for transitive models of second-order set theory. The

⁷It is unfortunate that mathematicians are not always careful about the distinction; for instance, one sometimes hears the Shepherdson–Cohen minimum transitive model called the *minimal* model of ZF, even though it satisfies the stronger property. And observe that the existence of a minimal transitive model of ZF is trivially proven from the assumption of the existence of a transitive model of ZF, simply by considering any model of minimum ordinal height. On the other hand, the Shepherdson and Cohen proofs that there is a minimum transitive model use considerable technology.

⁸To clarify, the superscript 0 and 1 refer to whether a formula includes quantification over classes, rather than the arithmetical/analytical hierarchies from descriptive set theory. The 0 is for first-order quantification; for instance, a Π_1^0 formula has a single unbounded universal set quantifier, with all other quantifiers bounded. The 1 is for second-order quantification; for instance, a Σ_1^1 formula is of the form $\exists X \varphi(X, P)$ where φ is Π_k^0 for some k .

⁹See observation 21.

trouble is that class relations can have rank $> \text{Ord}$ so we cannot use the Δ_0^0 definition of the von Neumann ordinals to get a Σ_1^0 characterization for well-foundedness. (Of course, well-foundedness for *set* relations is upward absolute for transitive models.)

Similar to the definitions of the minimum transitive model of T , a T -realization for M , a T -realizable model, and the minimum T -realization for M we can define the *minimum β -model of T* , a *β - T -realization for M* , a *β - T -realizable model*, and the *minimum β - T -realization for M* . For instance, $\mathcal{X} \subseteq \mathcal{P}(M)$ is a *β - T -realization for M* if $(M, \mathcal{X}) \models T$ is a β -model. I will also use $\mathcal{X}_{\beta, T}(M)$ to refer to the intersection of β - T -realizations for M .

The convention in this paper when talking about formulae in the language of set theory is to use capital letters for classes and class variables and lowercase letters for sets and set variables. For example, the formula $\forall X \exists y y \in X$ gives the (false) proposition that every class has some set as a member.

Definition 7. Kelley-Morse set theory KM is the second-order set theory consisting of the following axioms:

- ZF for the first-order part;
- Extensionality for classes;
- Class Replacement, asserting that the image of any set under a class function is a set;
- The Comprehension axiom schema, namely the axioms $\forall \bar{P} \exists A \forall x x \in A \Leftrightarrow \varphi(x, \bar{P})$, for every second-order formula $\varphi(x, \bar{P})$. That is, φ can include quantifier over sets or over classes.

KM can be augmented with Global Choice GC, asserting that there is a bijection between V and Ord , to get KMC. In general, my convention will be that if BAR is a second-order set theory I will use BARC to mean BAR + GC.

Gödel–Bernays set theory GB is axiomatized similarly, except that the Comprehension schema is weakened. Its axioms are ZF for the first-order part, Extensionality for classes, Class Replacement, and the Elementary Comprehension schema. This is a subschema of the Comprehension schema where we restrict to only formulae which do not include class quantifiers. Following the convention for theories with Global Choice, GBC is GB + GC. We can consider other restrictions of the Comprehension schema to get a hierarchy of theories ranging in strength from GB to KM. For a natural number k , let Π_k^1 -CA denote the restriction of Class Comprehension to the Π_k^1 -formulae. Then GB + Π_0^1 -CA is just GB and KM is GB + $\bigcup_{k \in \omega} \Pi_k^1$ -CA. Levels of this hierarchy are separated in terms of consistency strength. That is, GB + Π_{k+1}^1 -CA proves the consistency of GB + Π_k^1 -CA. In this article we will also see Δ_1^1 -CA, Comprehension for Δ_1^1 -properties.¹⁰

Observe that Class Replacement together with Elementary Comprehension yield that Separation and Replacement hold allowing classes as parameters.

Intermediate between Π_0^1 -CA and Π_1^1 -CA is the principle ETR of Elementary Transfinite Recursion. This schema asserts that if φ is a first-order formula (possibly with class parameters) and R is a well-founded class relation then there is a solution to the recursion of φ along R . Formally, let $\varphi(x, Y, A)$ be a first-order formula, possibly with a class parameter A and let R be a well-founded class relation. Denote by $<_R$ the transitive closure of R . The instance of ETR for φ and R asserts that there is a class $S \subseteq \text{dom } R \times V$ which satisfies

$$S_r = \{x : \varphi(x, S \upharpoonright r, A)\}$$

¹⁰To be clear, instances of Δ_1^1 -CA have the form

$$\forall \bar{P} ([\forall x \forall Y \varphi(x, Y, \bar{P}) \Leftrightarrow \exists Y \psi(x, Y, \bar{P})] \Rightarrow \exists A \forall x [x \in A \Leftrightarrow \forall Y \varphi(x, Y, \bar{P})]),$$

where φ and ψ have no class quantifiers.

for all $r \in \text{dom } R$. Here, $S_r = \{x : (r, x) \in S\}$ denotes the r -th slice of S and

$$S \upharpoonright r = S \cap (\{r' \in \text{dom } R : r' <_R r\} \times V)$$

is the partial solution below r . It is equivalent to define ETR by restricting the well-founded relations allowed to well-founded partial orders, or to well-founded trees, or to well-orders; see [GH17, lemma 7].

One well-known class recursion is the Tarskian definition of truth. This recursion takes place over a proper class tree of height ω . Thus, ETR asserts the existence of a first-order truth predicate and hence proves $\text{Con}(\text{ZF})$, as restricting the truth predicate to parameter-free formulae gives a consistent completion of ZF .¹¹ This shows that ETR exceeds GB in consistency strength. For an upper bound, one can use $\Pi_1^1\text{-CA}$ to show that there is no least failure of a potential solution to an elementary recursion and from that conclude that a solution must exist. Indeed, $\text{GB} + \text{ETR} + \Delta_1^1\text{-CA}$ proves the consistency of $\text{GB} + \text{ETR}$ [Sat14, theorem 33]. In particular, $\text{GB} + \Pi_1^1\text{-CA}$ proves the consistency of $\text{GB} + \text{ETR}$. (And we can add Global Choice to both theories here and the result remains true.)

A useful fact is that Elementary Transfinite Recursion is equivalent to having solutions to a certain class of recursions. See [Fuj12, Corollary 61] and [GH17, Theorem 8].

Theorem 8. *Over GB, Elementary Transfinite Recursion is equivalent to the assertion that for every class A and every class well-order Γ there is a Γ -iterated first-order truth predicate relative to A .*

A Γ -iterated truth predicate is a class T of triples (a, φ, p) where $(a, \varphi, p) \in T$ intuitively means that $\varphi(p)$ is true at level $a \in \text{dom}(\Gamma)$. Here, φ is in the language with \in and a predicate symbol \hat{T} for T . Formally, this is defined by a modified form of the Tarskian recursion, with an extra clause in the definition asserting that $(a, \ulcorner \hat{T}(x, y, z) \urcorner, \langle b, \varphi, p \rangle) \in T$ if and only if $b <_\Gamma a$ and $(b, \varphi, p) \in T$. A truth predicate relative to A is for the language expanded with a predicate symbol \hat{A} for A , with an extra clause in the definition asserting that $(a, \ulcorner \hat{A}(x) \urcorner, p) \in T$ if and only if $p \in A$.

It can be proven from GB that any two would-be Γ -iterated truth predicates relative to A must be the same class: By Elementary Comprehension we can form the class of indices where they disagree, and so if they disagree they must disagree at a minimal point, from which we can derive a contradiction. I will use $\text{Tr}_\Gamma(A)$ to refer to the unique Γ -iterated truth predicate relative to A . Iterated truth predicates not relative to any class will be denoted Tr_Γ . As a special case, $\text{Tr}(A) = \text{Tr}_1(A)$ is the ordinary truth predicate relative to A .

I include a brief proof sketch for theorem 8 below, in order to illustrate that we in fact get a stronger result. For a full proof see the above cited literature.

Proof sketch of theorem 8. (\Rightarrow) Construct $\text{Tr}_\Gamma(A)$ by means of a recursion of rank $\omega \cdot \Gamma$.

(\Leftarrow) Given $\text{Tr}_\Gamma(A)$ one can construct a solution to a recursion of φ (with parameter A) along a relation of rank Γ . \square

As an immediate corollary of this proof we get the following.

¹¹If the model is ω -nonstandard, meaning that its ω is ill-founded, things are a little more delicate. The model will still think that ZF is consistent because what it thinks is ZF, nonstandard instances of the axiom schemata and all, will be contained in what it thinks is the first-order theory of the model, which it necessarily thinks is complete and consistent.

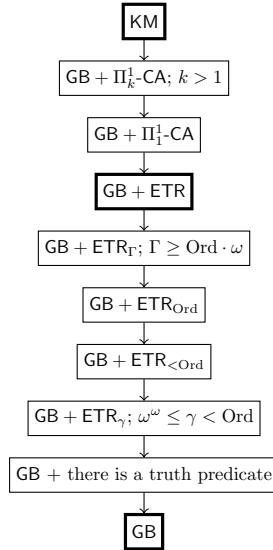

Definition 9. For a class well-order Γ , let ETR_Γ denote the principle of Elementary Transfinite Recursion restricted to relations of rank $\leq \Gamma$ and let $\text{ETR}_{<\Gamma}$ denote the restriction of Elementary Transfinite Recursion to relations of rank $< \Gamma$.

Corollary 10. *If $\omega^\omega \leq \Gamma$ then ETR_Γ is equivalent over GB to the existence of Γ -iterated truth predicates relative to any class.*

Proof. The assumption on Γ implies that $\omega \cdot \Gamma < \Gamma + \Gamma$. Because ETR_Γ implies $\text{ETR}_{\Gamma+\Gamma}$ (and $\text{ETR}_{\Gamma \cdot n}$ for all standard n), this gives that we can do the necessary recursions of rank $\omega \cdot \Gamma$. \square

It must be clarified just what it means for a model to satisfy ETR_Γ . If $\Gamma \in \mathcal{X}$ then it makes sense to ask whether (M, \mathcal{X}) satisfies ETR_Γ —simply use Γ as a parameter. However, this approach flounders upon the questions of whether there is a minimum β -model of or a minimum transitive model of $\text{GB} + \text{ETR}_\Gamma$. How should Γ be interpreted if we do not already have a model in mind?

To handle this context, suppose Γ is a name for a class well-order, meaning Γ is defined by some formula which GB proves defines a well-order. For example, Γ could be ω^ω , ω_1 , Ord, or some other definable well-order. I will slightly abuse notation and use ETR_Γ in this context, referring to the theory in the language with \in as its only non-logical symbol. And $\text{ETR}_{<\Gamma}$ is similarly used in this context. One natural instance of this is ETR_{Ord} , asserting that recursions of rank $\leq \text{Ord}$ have solutions.¹² Different models will have different Ords, but since GB proves that Ord is a well-order, it always is sensible to ask whether (M, \mathcal{X}) satisfies ETR_{Ord} .

Some second-order set theories from GB to KM, separated by consistency strength.

2.1. Models of second-order set theories. In the interest of completeness of presentation, I will summarize some well-known facts about how we construct models of these second-order set theories.

¹²To briefly attempt to justify the naturalness of ETR_{Ord} , Gitman, Hamkins, Holy, Schlicht, and myself showed [GHHSW17] that ETR_{Ord} exactly captures the strength of the forcing theorem for class forcings, along with several other principles.

Let $M \models \text{ZF}$. Say that $A \subseteq M$ is *strongly amenable (to M)* if $(M, A) \models \text{ZF}(A)$, where $\text{ZF}(A)$ is the expansion of ZF obtained by allowing a predicate symbol for A in the axiom schemata of ZF . If A is strongly amenable then A is *amenable*, meaning that for $A \cap x$ is a set in M for any $x \in M$. Observe that every class in a model of GB is strongly amenable to the first-order part.

The following observation is key in constructing models of GB and GBC .

Observation 11. *Let M be a model of ZF and suppose $A \subseteq M$ is strongly amenable. Then $\text{Def}(M; A)$ is a GB -realization for M , where $\text{Def}(M; A)$ is the collection of classes of M first-order definable from A and set parameters. If a global well-order of M is definable from A , then $\text{Def}(M; A)$ is a GBC -realization for M .*

In particular, $\text{Def}(M) = \text{Def}(M; \emptyset)$ is always a GB -realization for M . So any model of ZF is GB -realizable. If M moreover has a definable (from parameters) global well-order then $\text{Def}(M)$ is a GBC -realization for M . Note that having a definable global well-order is equivalent to satisfying the axiom $\exists x V = \text{HOD}(\{x\})$, where $\text{HOD}(\{x\})$ denotes the (definable) class of all sets hereditarily definable from ordinal parameters and x . (Having a global well-order definable without parameters is equivalent to $V = \text{HOD}$.) Therefore, any model of $\text{ZFC} + \exists x V = \text{HOD}(\{x\})$ is GBC -realizable.

We can do better. Any countable model of ZFC has a GBC -realization, even if it does not have a definable global well-order. This can be seen by a class forcing argument, which was originally noticed by several mathematicians, among them Cohen, Felgner, and Solovay. Of these, only Felgner published the argument [Fel71; Fel76]. Gaifman later found a forcing-free model-theoretic proof [Gai75]. To sketch the argument: If C is a Cohen-generic subclass of Ord , then by density C codes a strongly amenable global well-order. If $M \models \text{ZFC}$ is countable we can find such $C \in V$ as we only need to meet countably many dense definable classes of M . This gives us $(M, \text{Def}(M; C)) \models \text{GBC}$ in V . As a consequence, GBC is conservative over ZFC . That is, any first-order theorem of GBC is a theorem of ZFC . In particular, $\text{GBC} \not\vdash \text{Con}(\text{ZFC})$, supposing GBC is consistent.

This construction does not generalize to uncountable models of ZFC . Say that a model of set theory is *rather classless* if its only amenable classes are its classes definable from set parameters. Note that the height of a rather classless model must have uncountable cofinality. Any ω -sequence cofinal in the ordinals of a model will be amenable because its initial segments are finite.

Definition 12. Let M be a model of set theory. An extension $N \supseteq M$ is an *end-extension* if M is a transitive subclass of N . That is, N end-extends M whenever given any $a \in M$, if $N \models b \in a$ then $b \in M$. And an end-extension $N \supseteq M$ is a *top-extension* or *rank-extension* if M is a rank-initial segment of N .

Note that top-extensions are end-extensions but the converse does not in general hold. However, if N is an elementary end-extension of $M \models \text{ZF}$ then it must be a top-extension: By elementarity, $V_\alpha^M = V_\alpha^N$ cannot have any new elements.

Theorem 13 (Keisler [Kei74], Shelah [She78]). *Any countable model of ZF has an elementary end-extension to a rather classless model.*¹³

If we start with countable $M \models \text{ZFC}$ with no definable global well-order, then any rather classless N which is an elementary extension of M has no amenable global well-order and therefore has no GBC -realization. That such M exists was proved by Easton in his doctoral dissertation [Eas64].¹⁴

¹³Keisler showed this theorem under the assumption of \diamond and the assumption of \diamond was later eliminated by Shelah.

¹⁴Easton's dissertation was published in the Annals of Mathematical Logic [Eas70], but this publication omits the section where he proves this result. See [Fel76, section 3] for a published copy of Easton's argument, or [Ham12] for a publicly available version of the argument on MathOverflow.

For stronger theories, such as KM or GB+ETR, we cannot hope for techniques as general as in the GB case. A significant obstacle is that these theories prove $\text{Con}(\text{ZF})$; consequently, a model of ZF can fail to have, say, a KM-realization simply by having the wrong theory. And we can separate models of these stronger theories in a similar way; for example, if $(M, \mathcal{X}) \models \text{GB} + \text{ETR} + \neg \text{Con}(\text{GB} + \text{ETR})$, then M cannot be KM-realizable.

For $M \models \text{ZF}$ to be KM-realizable it must satisfy the first-order consequences of KM. But this condition is in fact insufficient. There is no theory whose models are all KM-realizable. In fact, we need much less than KM for this.

Theorem 14 (Krajewski [MM75, page 475]). *There is no first-order theory all of whose models (or even just whose countable models) are $(\text{GB} + \text{ETR}_\omega)$ -realizable. That is, given any consistent T extending ZF there is a countable model of T which has no $(\text{GB} + \text{ETR}_\omega)$ -realization.*

Proof. First suppose that M is a model of T and \mathcal{X} is an $(\text{GB} + \text{ETR}_\omega)$ -realization for M . (If no model of T is $(\text{GB} + \text{ETR}_\omega)$ -realizable we are already done.) Consider $\text{Tr} \in \mathcal{X}$, the truth predicate for M , which exists as it can be constructed by an elementary recursion of ω . By reflection, there is a club of ordinals $\alpha \in \text{Ord}^M$ so that $(V_\alpha^M, \text{Tr} \cap V_\alpha^M)$ thinks that $\text{Tr} \cap V_\alpha^M$ satisfies the recursive Tarskian definition of truth. If M is ω -standard, meaning that ω^M is well-founded, then Tr is the real truth predicate for M . If M is ω -nonstandard, then Tr restricted to the standard formulae is truth for M . In either case, we get that $V_\alpha^M \subseteq M$ satisfies the full elementary diagram of M and hence is elementary in M . Moreover, these V_α^M form an elementary tower which unions up to M . Altogether, we have seen that the first-order part of any model of ETR_ω must be the union of an elementary tower from its V_α s. In particular, any ETR_ω -realizable model must contain many undefinable ordinals.

On the other hand, Paris showed [Par73] that every T extending ZF has a model whose every ordinal is definable without parameters. Such models are now known as *Paris models*.¹⁵ The previous paragraph shows that no Paris model can be ETR_ω -realizable, and thus no first-order theory can characterize the ETR_ω -realizable models. \square

One take-away from this is that constructing models of stronger second-order set theories is less straightforward than constructing models of GB or GBC. This topic for ETR will be taken up in section 5. For KM, probably the simplest way to produce a model comes from looking at inaccessible cardinals: if κ is inaccessible, then $(V_\kappa, V_{\kappa+1}) \models \text{KM}$. Of course, once we have any transitive model of KM we get countable transitive models by Löwenheim–Skolem. Indeed, $(V_\kappa, V_{\kappa+1})$ satisfies more than just KM.

Definition 15. The *Class Collection* axiom schema asserts that if for every set there is a class satisfying some property, then there is a single class coding the “meta-class” consisting of a witnessing class for every set. Formally, instances of this schema take the form

$$\forall \bar{P} [(\forall x \exists Y \varphi(x, Y, \bar{P})) \Rightarrow (\exists C \forall x \exists i \varphi(x, (C)_i, \bar{P}))],$$

where $(C)_i = \{y : (i, y) \in C\}$.

The *Class Choice* axiom schema strengthens Class Collection to have that the index of the witnessing class for x is x itself. That is, instances of Class Collection have the form

$$\forall \bar{P} [(\forall x \exists Y \varphi(x, Y, \bar{P})) \Rightarrow (\exists C \forall x \varphi(x, (C)_x, \bar{P}))].$$

Proposition 16. *Over GB, Class Choice is equivalent to Class Collection plus Global Choice.*

¹⁵The name Paris model comes from [Ena05], which contains a thorough investigation of their properties.

Proof. (\Rightarrow) It is immediate that Class Collection follows from Class Choice. To see that Global Choice also follows, observe that for each $x \neq \emptyset$ there is a singleton class $Y \subseteq x$. We do not need any fragment of choice beyond that afforded by first-order logic to make this conclusion. So by Class Choice there is a class C so that for each $x \neq \emptyset$ we have $(C)_x \subseteq x$ is a singleton. Now define a class function $F : V \setminus \{\emptyset\} \rightarrow V$ by setting $F(x)$ to be the unique element of $(C)_x$. It is clear that such F is a global choice function, the existence of such being one equivalent formulation of Global Choice.

(\Leftarrow) Suppose for each x there is Y so that $\varphi(x, Y, P)$ for some fixed parameter P . By Class Collection there is a class D so that for each x there is i so that $\varphi(x, (D)_i, P)$. Now define a new class C by putting (x, y) into C if and only if $(i_x, y) \in D$ where i_x is least, according to a fixed global well-order, so that $\varphi(x, (D)_{i_x}, P)$. Then C witnesses the instance of Class Choice for $\varphi(x, Y, P)$. \square

It can be readily checked that if κ is an inaccessible cardinal, then $(V_\kappa, V_{\kappa+1}) \models \text{KM} + \text{Class Collection}$. If AC holds in the background universe, it will moreover satisfy Global Choice, and hence Class Choice. Indeed, every model of $\text{KM} + \text{Class Collection}$ looks like the $(V_\kappa, V_{\kappa+1})$ of some appropriate model of set theory.

Definition 17. Let ZF_1^- denote the theory whose axioms are those of ZF^- (namely, the axioms of ZF without Powerset but axiomatized with Separation and Collection instead of Replacement¹⁶) along with the assertion that there is a largest cardinal κ and that κ is inaccessible. To be clear since in this context not all sets have powersets, the assertion that κ is inaccessible is: κ is regular, V_κ exists, and for every $a \in V_\kappa$ we have that $\mathcal{P}(a)$ exists and is an element of V_κ . And let ZFC_1^- be the theory obtained from ZF_1^- by adding the assertion that every set can be well-ordered.

Marek and Mostowski [MM75] showed that $\text{KM} + \text{Class Collection}$ and ZF_1^- are bi-interpretable, as are $\text{KMC} + \text{Class Collection}$ and ZFC_1^- . The backward direction is simple. Namely, if $M \models \text{ZF}_1^-$ with largest cardinal $\kappa \in M$ then one can straightforwardly see that $(V_\kappa^M, V_{\kappa+1}^M) \models \text{KM} + \text{Class Collection}$. To have a name for this, call it the *cutting-off construction*.

The forward interpretation goes through what I will call the *unrolling construction*. The idea is, just as we can code hereditarily countable sets as subsets of ω , we can code ‘sets’ of rank $> \text{Ord}$ via certain class relations. Call a well-founded, extensional binary relation with a maximum element a *membership code*. These are the representatives of the sets in the unrolled structure, where we identify isomorphic membership codes. For example, $\in \upharpoonright \text{tc}(\{x\})$ is a membership code which represents the set x . We can define a suitable membership relation between membership codes—namely A is a member of B if there is a predecessor a to the maximum element of B so that A is isomorphic to the restriction of B below a . One can then show that this structure satisfies all of ZF_1^- . And if one carries out one interpretation then the other, the resulting model is isomorphic to the original model.¹⁷

In section 6 I will use that the unrolling construction can be carried out over models satisfying much less than KM. The key facts are the same as in the $\text{KM} + \text{Class Collection}$ case. Namely, if (M, \mathcal{X}) satisfies a strong enough theory to carry out the unrolling construction then carrying out the unrolling construction followed by the cutting construction produces a model isomorphic to (M, \mathcal{X}) , and this isomorphism is definable. And the same holds for cutting off followed by unrolling. In my dissertation, I show that $\text{GB} + \text{ETR}$ suffices to carry out the unrolling construction to get a structure

¹⁶In the absence of Powerset, Collection is stronger than Replacement [Zar96].

¹⁷Antos and S. Friedman [AF17] consider a different version of this construction, where they use trees for coding rather than well-founded extensional graphs. Their construction gives the same bi-interpretability result.

which satisfies an appreciable basic set theory [Wil18, chapter 2].¹⁸ To give more detail: GB alone is enough to define the unrolled structure, with an appropriate membership relation between well-founded, extensional class relations. To see that the unrolled structure satisfies basic axioms of set theory, enough to carry out the cutting off construction, I went through the key lemma that between two well-founded, extensional class relations A and B there is a maximum initial partial isomorphism.¹⁹ From this lemma one can prove that the unrolled structure satisfies Extensionality, Pairing, and other basic axioms of set theory, including Π_0 -Separation and Transfinite Recursion for Π_0 -properties. This lemma is an easy consequence of ETR, since the maximum initial partial isomorphism is built by an elementary transfinite recursion along either A or B . I conjecture that this lemma cannot be proven from GB alone. Specializing this lemma to the case where A and B are well-orders we get that class well-orders are comparable.

Conjecture. GB does not prove the comparability of class well-orders, asserting that given any two class well-orders Γ and Δ one embeds as an initial segment of the other.

To end this section, I wish to remark that when looking at the phenomenon of minimum models moving from KM to KM + Class Collection is harmless.

Theorem 18 (Marek and Mostowski [MM75, theorem 2.5]). *Let $(M, \mathcal{X}) \models \text{KM}$ and let $N \in \mathcal{X}$ be an inner model of M . Then there is $\mathcal{Y} \subseteq \mathcal{X}$ so that $(N, \mathcal{Y}) \models \text{KM} + \text{Class Collection}$. If N has a global well-order in \mathcal{X} , then \mathcal{Y} may be picked so that (N, \mathcal{Y}) satisfies Global Choice, and hence also Class Choice.*

Ratajczyk showed [Rat79] that an appropriate version of Marek and Mostowski's theorem holds with KM replaced by GB + Π_1^1 -CA,²⁰ and a restricted form of Class Collection.

3. HISTORICAL BACKGROUND

Before moving to the novel content in this article, I wish to place my results in the context of previous work. The first result in this theme I will mention is a classical theorem, due to Marek and Mostowski [MM75]. They proved that every β -KM-realizable model has a minimum β -KM-realization.²¹ As an immediate corollary, if M has a definable global well-order and is β -KM-realizable then it has a minimum β -KMC-realization. And it then follows from observation 21 below that if M is β -KM-realizable then M has a minimal KM-realization, which is moreover a minimal KMC-realization.

Their methods were improved by Ratajczyk [Rat79] to apply not just to KM but also to GB + Π_k^1 -CA, for $k \geq 1$. This yields the same results from the previous paragraph but with KM replaced with GB + Π_k^1 -CA.

More recently, Antos and S. Friedman [AF17] investigated what they call minimal β -models of MK^{**} , a certain strengthening of KMC + Class Collection. They showed that if (M, \mathcal{X}) is a countable β -model of MK^{**} then it can be expanded by hyperclass forcing to a β -model (N, \mathcal{Y}) of MK^{**} containing a certain real r which is minimum among β -models of MK^{**} containing r . My main theorem 3 can be strengthened to show that if T is a fixed computably axiomatizable extension of KM, then given any real r there is never a transitive model of T which is minimum among those

¹⁸Global Choice is taken as a basic axiom in that chapter, but it is straightforward to see that it is not necessary to carry out the unrolling construction and prove basic facts about the unrolled structure.

¹⁹An initial partial isomorphism is a partial isomorphism whose domain and range are both downward closed.

²⁰Ratajczyk refers to this theory as KM_1 .

²¹See theorem 47 below.

transitive models of T containing r ; see theorem 49. I view this as justifying Antos and Friedman’s restriction to looking only at β -models. They justify this restriction, in their footnote 3, by analogy to ZFC, saying that it is only sensible to talk about minimum models when restricting to the class of models correct about well-foundedness. In my view, this analogy is ill-founded. As other results in the current paper show, there can be minimum models in collections of models which contain non- β -models. Or for an example from first-order set theory: $L_{\omega_1^{\text{CK}}}$ is the minimum transitive model of $\text{KP} + \text{Infinity}$. But $L_{\omega_1^{\text{CK}}}$ is not a β -model; Harrison showed [Har68] there are computable linear orders which are ill-founded but have no infinite descending chain in $L_{\omega_1^{\text{CK}}}$. Nevertheless, Antos and Friedman’s restriction to β -models is necessary to achieve such a result in their context.

Also important to mention in this context is that the class of transitive models of KM is strictly larger than the class of β -models of KM. Indeed, Marek and Mostowski showed [MM75, theorem 3.2] that if τ is the least height of a transitive model of KM and β is the least height of a β -model of KM, then $\tau < \beta$ and $L_\beta \models \tau$ is countable. Applying Ratajczyk’s improvements gives an analogous result for $\text{GB} + \Pi_k^1\text{-CA}$, for $k \geq 1$.

Moving from models of second-order to a more general context, the same questions can be asked about other second-order theories. The analogies and disanalogies between the second-order set theory and second-order arithmetic have received considerable attention, much of it from the Warsaw school of logicians centered around Mostowski. Similar questions to the ones I study in this article have been asked and answered in the context of second-order arithmetic. Before I review those results, let me briefly describe the setting for second-order arithmetic.

Models of second-order arithmetic are two-sorted. One sort, the first-order part of the model, consists of the numbers, while the other, the second-order part, consists of sets of numbers. The chief axiom for the numbers is induction, and the sets are axiomatized by principles similar to those for classes in second-order set theory. This produces the following analogy between theories of arithmetic and set theories. (I omit mention of RCA_0 and WKL_0 , the weakest of the “Big Five” theories of second-order arithmetic, as this paper does not study any set theoretic analogues thereof.)

Arithmetic	Set Theory
PA	ZF
ACA_0	GB
ATR_0	GB + ETR
$\Pi_k^1\text{-CA}_0$	GB + $\Pi_k^1\text{-CA}$
Z_2	KM

In set theory, there are a plethora of different first-order models whose membership relation is well-founded. In arithmetic on the other hand, there is a unique first-order model which is well-founded, namely ω . Those models of second-order arithmetic with ω as their first-order part are appropriately known as ω -models. It is common practice to identify ω -models with their second-order part, speaking for example of the ω -model HYP rather than (ω, HYP) . Those ω -models which are moreover correct about which of their sets are well-founded are called β -models. The following are some of the results about minimum/minimal ω - and β -models of arithmetic.²² Below, ARITH is the collection of arithmetical subsets of ω and HYP is the collection of hyperarithmetical subsets of ω .

²²The reader who wishes to know more is advised to consult [Sim09], especially chapter VIII. In particular, they can find therein proofs and references for the following theorems.

Theorem (Mostowski). *ARITH is the minimum ω -model of ACA_0 . In general, if $M \models \text{PA}$ then $\text{Def}(M)$, the collection of parametrically definable subsets of M is the minimum ACA_0 -realization for M .*

Theorem (Kleene). *HYP is the minimum ω -model of $\Delta_1^1\text{-CA}_0$, whose principal axiom is Δ_1^1 -Comprehension.*

Theorem (Gandy-Kreisel-Tait). *HYP is the intersection of all ω -models of Z_2 . Indeed, the same holds with Z_2 replaced with any computably axiomatizable extension of $\Sigma_1^1\text{-AC}_0$ (in the language of second-order arithmetic).²³*

Combined with the fact that $(\omega, \text{HYP}) \not\models \Sigma_1^1\text{-AC}_0$, this theorem immediately implies that no computably axiomatizable extension of $\Sigma_1^1\text{-AC}_0$ has a minimum ω -model. In particular, Z_2 has no minimum ω -model.

Theorem (Simpson). *HYP is the intersection of all ω -models of ATR_0 . And the same holds if we restrict to β -models. In particular, ATR_0 has no minimum β -model.*

Theorem (Gandy). *Z_2 has a minimum β -model.*

Simpson showed that the same holds for ATR_0 and $\Pi_k^1\text{-CA}_0$, for $k \geq 1$.

Theorem (H. Friedman). *There is no minimal ω -model of Z_2 .*

Theorem (Quinsey). *Let T be a computably axiomatizable extension of ATR_0 in the language of second-order arithmetic. Let $(M, \mathcal{X}) \models T$ be countable. Then there is $Y \subsetneq \mathcal{X}$ so that $(M, \mathcal{Y}) \models T$. That is, no countable $M \models \text{PA}$ has a minimal T -realization. In particular, T has no minimal ω -model.*

Several of these results have reflections upward in the set theoretic realm. For example, that Z_2 has no minimum ω -model is the arithmetic counterpart to the fact that KM has no minimum transitive model. I want to highlight one case where there is a known disanalogy. Simpson's result that there is no minimum β -model of ATR_0 does not carry over to the set theoretic realm. Main theorem 4 is that there is a minimum β -model of $\text{GB} + \text{ETR}$. The underlying reason for this disanalogy is that in set theory, a class being well-founded is an elementary property, whereas in arithmetic it is a Π_1^1 property, and in fact is Π_1^1 -universal. As will be made clear in section 5, my construction of the minimum β -model of $\text{GB} + \text{ETR}$ heavily uses that submodels of β -models of set theory with the same first-order part are automatically β -models, a fact that follows immediately from well-foundedness being elementary. From the other direction, Simpson's argument uses that being well-founded is Π_1^1 -universal in arithmetic. This is the source of other disanalogies between $\text{GB} + \text{ETR}$ and ATR_0 ; see e.g. [Sat14] or [Fuj12].

4. GB

Let us begin with a classical result.

Theorem 19 (Shepherdson [She53]). *If there is a transitive model of GB then there is a minimum transitive model of GB , and it moreover satisfies Global Choice.*

²³See [Sim09, section VIII.4] for a definition of $\Sigma_1^1\text{-AC}_0$, whose principal axiom is the axiom of choice for Σ_1^1 definable collections of sets. The reader should also be aware that ATR_0 proves every instance of the schema of $\Sigma_1^1\text{-Choice}$.

Proof. Let L_α be the minimum transitive model of ZFC. Then $(L_\alpha, \text{Def}(L_\alpha)) = (L_\alpha, L_{\alpha+1})$ is the minimum transitive model of GBC. If (M, \mathcal{X}) is a model of GBC whose height is α , then $L_{\alpha+1} \subseteq \mathcal{X}$ because L is a definable class. If the height of M is greater than α , then $L_{\alpha+1} \subseteq M$. Finally, note that it satisfies Global Choice because the L -order is definable. \square

Essentially the same argument gives the following.

Corollary 20. *If there is a β -model of GB then there is a minimum β -model of GB, and it satisfies Global Choice.*

The key to proving this is the following observation.

Observation 21.

- (1) *Let $M \models \text{ZF}$. If $(M, \mathcal{X}) \models \text{GB}$ is a β -model and $\mathcal{Y} \subseteq \mathcal{X}$ then (M, \mathcal{Y}) is a β -model.*
- (2) *Moreover, if $(M, \mathcal{X}) \models \text{GB}$ is a β -model and $(N, \mathcal{Y}) \models \text{GB}$ is such that $\text{Ord}^N = \text{Ord}^M$, $N \subseteq M$, and $\mathcal{Y} \subseteq \mathcal{X}$, then (N, \mathcal{Y}) is a β -model.*

Proof. (1) This follows immediately from the fact that “ R is a well-founded class relation” can be expressed via a first-order formula. Namely, I claim that, over GB, a binary relation R is well-founded if and only if every nonempty set $d \subseteq \text{dom } R$ has a minimal element. Clearly, every well-founded relation satisfies this property. For the other direction, suppose that R is ill-founded. Let α_0 be least so that V_{α_0} contains $x \in \text{dom } R$ so that the class $R \upharpoonright x = \{(y, y') \in R : y, y' <_R x\}$, where $<_R$ is the transitive closure of R , is ill-founded. Let $X_0 \subseteq V_{\alpha_0}$ be the set of such x . Given α_n and X_n , let α_{n+1} be least such that for each $x' \in X_n$ we have $V_{\alpha_{n+1}}$ contains some $x R x'$ for which $R \upharpoonright x$ is ill-founded. And set $X_{n+1} \subseteq V_{\alpha_{n+1}}$ to be the set of these x . Finally, set $X = \bigcup_{n \in \omega} X_n$. Then X is a set and $R \upharpoonright X$ is an ill-founded set-sized subrelation of R . So there is some $d \subseteq X$ without an R -minimal element.

(2) Suppose $R \in \mathcal{Y}$ is ill-founded. Then (M, \mathcal{X}) thinks that R is ill-founded, so there is $d \in M$ witnessing this. Let $\theta \in \text{Ord}^M$ be so that $d \in V_\theta^M$. Set $r = R \cap V_\theta^N \in N$. Then $r \in M$ because $N \in \mathcal{Y} \subseteq \mathcal{X}$. Observe that r is ill-founded, as M sees that d witnesses the ill-foundedness of r . But r is a set in N which is a transitive model of ZFC. So N must think r is ill-founded and hence (N, \mathcal{Y}) thinks R is ill-founded. \square

Proof of corollary 20. Consider $(L_\alpha, \text{Def}(L_\alpha))$, where α is least such that there is a β -model of GB of height α . Let $(M, \mathcal{X}) \models \text{GB}$ be a β -model with $\text{Ord}^M = \alpha$. Then $L_\alpha \supseteq M$ and $\text{Def}(L_\alpha) \subseteq \mathcal{X}$. By the observation, $(L_\alpha, \text{Def}(L_\alpha)) \models \text{GBC}$ is a β -model. It must be contained in every β -model of GB. \square

More interesting is the question of when there is a minimum GBC-realization for a model of ZFC. Note that this is not interesting if we do not include Global Choice, as $\text{Def}(M)$ is always the minimum GB-realization for M .

Theorem 22 (Main theorem 1). *Let M be a countable model of ZFC. Then M has a minimum GBC-realization if and only if M has a parametrically definable global well-order.*

Proof. (\Leftarrow) Any GBC-realization for M must contain $\text{Def}(M)$. If M has a definable global well-order then $\text{Def}(M)$ is itself a GBC-realization, hence it is the minimum GBC-realization for M .

(\Rightarrow) Suppose towards a contradiction that \mathcal{X} is the minimum GBC-realization for M . As M has no definable global well-order, it must be that $\mathcal{X} = \text{Def}(M; G)$, where $G \notin \text{Def}(M)$ is some global well-order of M . Consider the forcing to add a Cohen subclass to Ord with set-sized conditions.

Note that this forcing does not add any new sets as it is κ -closed for every κ . Let H be (M, \mathcal{X}) -generic for this forcing. That is, H meets every dense class in \mathcal{X} . Then every set $a \in M$, is coded into H . To expound, ZF proves that every set a is uniquely determined by the isomorphism type of the graph $E_a = (\text{tc}(\{a\}), \in \upharpoonright \text{tc}(\{a\}))$. Now use Choice to take an isomorphic copy of E_a on the ordinals and look at its image under your favorite Σ_0 -definable pairing function $\text{Ord}^2 \rightarrow \text{Ord}$. This gives an ordinal-length binary sequence s_a from which we can recover a . Indeed, a is constructible from s_a . By density, every ordinal-length binary sequence is coded into H , and thereby every set is coded into H . This yields a global well-order definable from H : say that $a <_H b$ if the index where a is first coded into H is less than the index where b is first coded into H . Therefore, $\text{Def}(M; H)$ is a GBC-realization for M .

I claim that $G \notin \text{Def}(M; H)$. Otherwise, there is a first-order formula φ , possibly with set parameters and H as a class parameter but where G does not appear as a parameter, so that $(M, \text{Def}(M; G, H)) \models \forall x x \in G \Leftrightarrow \varphi(x, H)$. There is some $p \in H$ forcing this statement; that is, there is $p \in H$ so that $(M, \text{Def}(M; G)) \models "p \Vdash \forall x x \in \check{G} \Leftrightarrow \varphi(x, \check{H})"$. Thus, $(M, \text{Def}(M; G)) \models "\forall x x \in G \Leftrightarrow p \Vdash \varphi(\check{x}, \check{H})"$ so for all $x \in M$, we have $x \in G$ if and only if $(M, \text{Def}(M; G)) \models [p \Vdash \varphi(\check{x}, \check{H})]$. But this formula doesn't depend upon G , so this happens if and only if $M \models [p \Vdash \varphi(\check{x}, \check{H})]$. Therefore $G \in \text{Def}(M)$, contradicting that M has no definable global well-order.

As $G \notin \text{Def}(M; H)$, it cannot be that $\mathcal{X} = \text{Def}(M; G) \subseteq \text{Def}(M; H)$, contradicting that \mathcal{X} is the minimum realization. So M cannot have a minimum GBC-realization, as desired. \square

As remarked in Section 2, a model of ZFC having a definable global well-order is equivalent to that model satisfying the first-order sentence $\exists x V = \text{HOD}(\{x\})$. Thus, whether a countable model of set theory has a minimum GBC-realization is recognizable from the theory of the model.

Corollary 23. *A countable model of ZFC has a minimum GBC-realization if and only if it satisfies $\exists x V = \text{HOD}(\{x\})$.* \square

Corollary 24. *Let $M \models \text{ZFC}$ be countable. Then $\mathcal{X}_{\text{GBC}}(M) = \text{Def}(M)$.*²⁴

Proof. If $\text{Def}(M)$ is a GBC-realization for M then it is the minimum GBC-realization, whence $\mathcal{X}_{\text{GBC}}(M) = M$. Otherwise, the argument from the proof of theorem 22 that $G \notin \text{Def}(M; H)$ applies to any $A \in \text{Def}(M; G) \setminus \text{Def}(M)$. Thus $\text{Def}(M; G) \cap \text{Def}(M; H) = \text{Def}(M)$ and so $\mathcal{X}_{\text{GBC}}(M) \subseteq \text{Def}(M)$. The other inclusion is trivial, giving the desired equality. \square

The construction used in the proof of theorem 22 does not show that any countable $M \not\models \exists x V = \text{HOD}(\{x\})$ lacks a *minimal* GBC-realization. The reason is that the $\text{Def}(M; G)$ and $\text{Def}(M; H)$ from the proof are incomparable. We have already seen one direction, that $\text{Def}(M; G) \not\subseteq \text{Def}(M; H)$. The other direction, that $\text{Def}(M; H) \not\subseteq \text{Def}(M; G)$, is because by genericity $H \notin \text{Def}(M; G)$. We get that $\text{Def}(M; G)$ is not the minimum GBC-realization, but left open is the possibility that it could be minimal.

Question 25. *Is there $M \models \text{ZFC} + \forall x V \neq \text{HOD}(\{x\})$ with a minimal GBC-realization \mathcal{X} for M ? Can this happen for countable M ?*

Answering this question in general seems difficult, but something can be said for special cases. First is a negative result that minimal GBC-realizations cannot come from Cohen forcing.

Proposition 26. *Consider $M \models \text{ZFC}$ and suppose $C \subseteq \text{Ord}^M$ is Cohen-generic. Then, $\text{Def}(M; C)$ is not a minimal GBC-realization.*

²⁴Recall definition 6.

Proof. Define C' as $\alpha \in C'$ if and only if $\alpha \cdot 2 + 1 \in C$. If we think of C as an Ord-length binary sequence, C' is what appears on the odd coordinates of C . It is a standard result about Cohen forcing that C' is Cohen-generic but $C \notin \text{Def}(M; C')$. Thus, $\text{Def}(M; C') \subsetneq \text{Def}(M; C)$ and so $\text{Def}(M; C)$ is not minimal. \square

If we want a model of ZFC with a minimal GBC-realization which is not minimum, we must start with a model without a definable global well-order. We want to add a strongly amenable global well-order to this model which is minimal in a certain sense. A natural place to look here is at generalizations of Sacks forcing. As is well-known, Sacks reals are minimal over the ground model. Can we generalize Sacks forcing to produce a minimal generic class of ordinals which codes a global well-order?

Generalizing Sacks forcing to add generic classes of ordinals has been considered before. Hamkins, Linetsky, and Reitz [HLR13] consider so-called “perfect generics”, an adaptation of a technique of Kossak and Schmerl [KS06] from models of arithmetic. Kossak and Schmerl’s technique is in turn an adaptation from Sacks forcing over ω . They produce minimal generics for countable models M of arithmetic, i.e. inductive $G \subseteq M$ so that for $A \in \text{Def}(M; G)$ either $A \in \text{Def}(M)$ or $G \in \text{Def}(M; A)$.

I do not see a way to use perfect generics to produce a minimal but not minimum GBC-realizations. Nevertheless, a related result can be achieved.

Theorem 27 (Main theorem 2). *Let $(M, \mathcal{X}) \models \text{GBC}$ be countable. Then there is $\mathcal{Y} \supseteq \mathcal{X}$ a GBC-realization which is minimal above \mathcal{X} : if $\mathcal{Z} \supseteq \mathcal{X}$ is a GBC-realization, then $\mathcal{Y} \subseteq \mathcal{Z}$.*

This theorem shows that the poset consisting of countable GBC-realizations of a fixed countable $M \models \text{ZFC}$ is not dense in a strong sense. For any \mathcal{X} in this poset there is $\mathcal{Y} \supseteq \mathcal{X}$ with no elements of the poset in between them. On the other hand, proposition 26 gives $\mathcal{Z} \supseteq \mathcal{X}$ so that the interval $(\mathcal{X}, \mathcal{Z})$ of intermediate GBC-realizations contains a dense linear order.

Before proving this theorem, it will be necessary to set up some machinery.

Work with a fixed countable $\mathfrak{M} = (M, \mathcal{X}) \models \text{GBC}$. Let \mathbb{B} denote the full Ord-length binary tree. For a perfect tree $\mathbb{P} \subseteq \mathbb{B}$, say that $\mathbb{Q} \subseteq \mathbb{P}$ is *n-deciding* for \mathbb{P} if for every Σ_n formula φ in the forcing language for M , there is an ordinal α so that if $p \in \mathbb{Q}$ has length greater than α then p decides φ . It is not hard to see that if $\mathbb{P} \in \mathcal{X}$ then we can find $\mathbb{Q} \in \mathcal{X}$ which is *n-deciding* for \mathbb{P} . Moreover, we can find such \mathbb{Q} which does not split below a fixed $\alpha \in \text{Ord}$.

Definition 28. A function $G : \text{Ord} \rightarrow 2$ is called a *perfect generic* if there is a sequence $\mathbb{B} = \mathbb{P}_0 \supseteq \mathbb{P}_1 \supseteq \dots \supseteq \mathbb{P}_n \supseteq \dots$ of perfect trees from \mathcal{X} so that $G = \bigcup (\bigcap_n \mathbb{P}_n)$ and \mathbb{P}_{n+1} is *n-deciding* for \mathbb{P}_n for all n .

A subtle point is that a perfect generic need not be fully generic over any of the \mathbb{P}_n . So the model generated by a perfect generic G , namely

$$\mathfrak{M}[G] = (M, \{X \subseteq M : X \in \text{Def}(M; G, A) \text{ for some } A \in \mathcal{X}\}),$$

need not be a class forcing extension of \mathfrak{M} . As such, we need to refine some standard facts about class forcing. I summarize them here. First, the forcing relation (for pretame forcings, such as the posets we will use) for formulae of bounded complexity is definable. That is, the relation $p \Vdash_{\mathbb{P}} \varphi$, confined to φ which are Σ_k is Σ_j -definable from \mathbb{P} for some $j > k$. (It does not matter for our purposes what this j is, just that it is finite.) Second, we need to refine the usual “forcing equals truth” lemma: For φ which are Σ_k there is $j > k$ so that for any $G \subseteq \mathbb{P}$ which is Σ_j -generic over \mathfrak{M} then $\mathfrak{M}[G] \models \varphi$ if and only if there is $p \in G$ so that $p \Vdash_{\mathbb{P}} \varphi$. This can be proved via a standard inductive argument, attending to the complexity of the definitions of the dense sets involved. In

short, the standard facts for forcing apply for partial generics, except that we must be careful to confine ourselves to things which are sufficiently simple.

Using these refined forcing facts, we can see that $\mathfrak{M}[G]$ will still satisfy GBC, despite not in general being a forcing extension. Extensionality, Global Choice, and Elementary Comprehension are immediate. To see $\mathfrak{M}[G]$ satisfies Class Replacement, take a class function F . Then F is definable by a Σ_k -formula for some k with parameters G and $A \in \mathcal{X}$. But then the behavior of F is forced by conditions in $\mathbb{P}_j \supseteq G$ for large enough $j > k$.

The following lemmata will be used to prove the theorem. They are set theoretic analogues of results from section 6.5 of [KS06].

Lemma 29. *Let $\varphi(x)$ be a formula in the forcing language and $\mathbb{P} \in \mathcal{X}$ be a perfect subtree of \mathbb{B} . There is $\mathbb{Q} \subseteq \mathbb{P}$ in \mathcal{X} so that one of the two cases holds:*

- (1) *There is an ordinal α so that for all ordinals ξ we have that all $p \in \mathbb{Q}$ of length greater than α decide $\varphi(\xi)$ (in \mathbb{P}) the same.*
- (2) *For every ordinal α there is $\beta > \alpha$ so that if $p, q \in \mathbb{Q}$ both have length β and $p \upharpoonright \alpha = q \upharpoonright \alpha$ then there is an ordinal ξ so that p and q decide $\varphi(\xi)$ differently (in \mathbb{P}).*

Proof. Fix k so that φ is a Σ_k formula. Take $\mathbb{P}' \subseteq \mathbb{P}$ a k -deciding subtree for \mathbb{P} . We may assume that there is a function $f : \mathbb{B} \rightarrow \mathbb{P}'$ which embeds the full binary tree onto the splitting nodes of \mathbb{P}' and that $f(s)$ decides $\varphi(\text{len } s)$. There are two cases. The first is that there is some $s \in \mathbb{B}$ so that for every $t, t' \succ_{\mathbb{B}} s$ if $\text{len } t = \text{len } t'$ then $f(t)$ and $f(t')$ decide $\varphi(\xi)$ the same for all ordinals ξ . In this case, set $\mathbb{Q} = \mathbb{P}' \upharpoonright f(s)$ and get the first conclusion in the lemma.

The second case is that this does not happen for any $s \in \mathbb{B}$. In this case, we can inductively define a $g : \mathbb{B} \rightarrow \mathbb{P}'$ as follows:

- Set $g(0) = f(0)$.
- Set $g(s \smallfrown 0) = p_0$ and $g(s \smallfrown 1) = p_1$, where p_0, p_1 are least (according to a fixed global well-order) so that $\text{len } p_0 = \text{len } p_1$ and there is an ordinal ξ so that p_0 and p_1 decide $\varphi(\xi)$ differently. Such p_0 and p_1 always exist, as otherwise we would be in the previous case.
- At limit stages take unions.

Set $\mathbb{Q} = \{p \in \mathbb{P}' : \exists s \in \mathbb{B} p \leq_{\mathbb{P}'} g(s)\}$. This yields the second conclusion in the lemma. \square

Observe that we used global choice in an essential manner here. There are possibly many choices for p_0 and p_1 in the successor stage of the construction of g . In order to guarantee that $g \in \mathcal{X}$ and hence that $\mathbb{Q} \in \mathcal{X}$, we need to uniquely specify a choice.

This puts us in a position to prove a minimality lemma for perfect generics.

Lemma 30. *Let $(M, \mathcal{X}) \models \text{GBC}$ be countable. Then there is a perfect generic $G \notin \mathcal{X}$ so that for any class A of ordinals definable from G (and possibly parameters from \mathcal{X}), either G is definable from A and parameters from \mathcal{X} or else $A \in \mathcal{X}$.*

Proof. Fix a cofinal sequence $\langle \alpha_n \rangle$ of ordinals and an enumeration $\langle \varphi_n(x) \rangle$ of formulae in the forcing language. We construct a descending sequence of perfect trees

$$\mathbb{B} = \mathbb{Q}_0 \supseteq \mathbb{P}_0 \supseteq \mathbb{Q}_1 \supseteq \mathbb{P}_1 \supseteq \cdots \supseteq \mathbb{Q}_n \supseteq \mathbb{P}_n \supseteq \cdots$$

so that \mathbb{P}_n is an n -deciding subtree of \mathbb{Q}_n which does not split below α_n and $\mathbb{Q}_{n+1} \subseteq \mathbb{P}_n$ is as in the previous lemma for φ_n . Our perfect generic is $G = \bigcup (\bigcap_n \mathbb{P}_n)$.

Consider a class of ordinals A defined from G and parameters in \mathcal{X} , where $G \Vdash x \in A \Leftrightarrow \varphi_n(x)$. Consider $\mathbb{Q}_{n+1} \subseteq \mathbb{P}_n$. If the first case from the previous lemma holds, then $A \in \mathcal{X}$ because $\xi \in A$ if and only if for every $p \in \mathbb{Q}_{n+1}$ the length of p being sufficiently long implies that $p \Vdash_{\mathbb{P}_n} \varphi_n(\xi)$. If the

second case of the previous lemma holds, then we can define G from A . In this case, $p \in \bigcap_n \mathbb{P}_n$ if and only if for every ordinal α there is $q >_{\mathbb{Q}_{n+1}} p$ of length greater than α so that $q \Vdash_{\mathbb{P}_n} \varphi_n(\xi) \Leftrightarrow \xi \in A$ for all ordinals ξ . From a definition of $\bigcap_n \mathbb{P}_n$ can easily be produced a definition for G . \square

Proof of theorem 27. We start with countable $(M, \mathcal{X}) \models \text{GBC}$. Let G be the perfect generic as in the minimality lemma. Set \mathcal{Y} to be the classes definable from G and parameters in \mathcal{X} . Then, \mathcal{Y} is a GBC-realization for M . Suppose that \mathcal{Z} is a GBC-realization so that $\mathcal{X} \subseteq \mathcal{Z} \subseteq \mathcal{Y}$. Consider arbitrary $A \in \mathcal{Z}$. We may assume that A is a class of ordinals by mapping A , via a fixed bijection $V \rightarrow \text{Ord}$ from \mathcal{X} , into the ordinals. By the minimality lemma, either G is definable from A or else $A \in \mathcal{X}$. Therefore, if $\mathcal{Z} \neq \mathcal{X}$ then G is definable from an element of \mathcal{Z} (with parameters from \mathcal{X}) and hence $\mathcal{Y} = \mathcal{Z}$. \square

As remarked earlier, Global Choice was used essentially in the proof of lemma 29. Proving this lemma without Global Choice would yield a construction for minimal but not minimum GBC-realizations. Namely, start with a countable $M \models \text{ZFC}$ with no definable global well-order. Let $\mathcal{X} = \text{Def}(M)$. Then (M, \mathcal{X}) is a model of GB which does not satisfy Global Choice. Applying the theorem to (M, \mathcal{X}) would yield a GBC-realization \mathcal{Y} for M which is minimal above \mathcal{X} . But since any GBC-realization must contain \mathcal{X} , this would give that \mathcal{Y} is a minimal GBC-realization for M .

Thus, the problem of constructing a minimal but not minimum GBC-realization can be reduced down to the problem of proving the minimality lemma for perfect generics without using choice. A similar question can be asked for ordinary Sacks forcing.

Question 31. *Is choice needed to prove the minimality lemma for Sacks forcing? That is, is it consistent that there are $M \models \text{ZF} + \neg \text{AC}$, $s \subseteq \omega^M$ Sacks-generic over M , and $A \in M[s]$ so that $M \subsetneq M[A] \subsetneq M[s]$?*

5. ETR AND ITS FRAGMENTS

The main result of this section is that there is a smallest β -model of $\text{GB} + \text{ETR}$. First, a warm-up.

Theorem 32. *If $M \models \text{ZF}$ is β -(GB + ETR)-realizable, then M has a minimum β -(GB + ETR)-realization. Moreover, if M has a definable global well-order then this minimum β -(GB + ETR)-realization satisfies Global Choice.*

Proof. Suppose $(M, \mathcal{Y}) \models \text{GB} + \text{ETR}$ is a β -model. Externally to (M, \mathcal{Y}) we will construct a (GB + ETR)-realization $\mathcal{X} \subseteq \mathcal{Y}$ for M and then see that the construction for \mathcal{X} gives the same (GB + ETR)-realization no matter which \mathcal{Y} we started with.

Let $\mathcal{X}_0 = \text{Def}(M)$. Observe that if M has a definable global well-order, (M, \mathcal{X}_0) satisfies Global Choice. Now, given \mathcal{X}_n , define \mathcal{X}_{n+1} to consist of all classes of M definable from elements of $\{\text{Tr}_\Gamma(A) : A, \Gamma \in \mathcal{X}_n \text{ and } \Gamma \text{ is a class well-order}\}$.²⁵ A few remarks are in order to clarify why this definition is well-formed. First, note that $\mathcal{X}_0 \subseteq \mathcal{Y}$ and thus (M, \mathcal{X}_0) is a β -model by observation 21. Second, if $\mathcal{X}_n \subseteq \mathcal{Y}$ then $\mathcal{X}_{n+1} \subseteq \mathcal{Y}$. This is because \mathcal{Y} must have iterated truth predicates relative to any of its classes and because \mathcal{Y} and \mathcal{X}_n agree on what class relations are well-founded, both being β -models. Inductively, this yields that each $\mathcal{X}_n \subseteq \mathcal{Y}$ is a β -model. Because each of these is a β -model, they agree with V on whether Γ is a well-order. Finally, because M is transitive it has unique iterated truth predicates relative to a given parameter.

Set $\mathcal{X} = \bigcup_n \mathcal{X}_n$, so that $\mathcal{X} \subseteq \mathcal{Y}$. Because \mathcal{X} is an increasing union of GB-realizations for M , it must be that \mathcal{X} itself is a GB-realization for M . And if M has a definable global well-order,

²⁵Recall that $\text{Tr}_\Gamma(A)$ denotes the Γ -iterated truth predicate relative to the class A , where Γ is a class well-order.

then (M, \mathcal{X}) moreover satisfies Global Choice. To see that (M, \mathcal{X}) satisfies Elementary Transfinite Recursion, note that if $A, \Gamma \in \mathcal{X}$ then $A, \Gamma \in \mathcal{X}_n$ for some n and thus $\text{Tr}_\Gamma(A) \in \mathcal{X}_{n+1} \subseteq \mathcal{X}$.

It remains only to see that we get the same \mathcal{X} regardless of our choice of \mathcal{Y} . But this is immediate, since \mathcal{Y} was not actually used to define the \mathcal{X}_n . We only used that $\mathcal{X}_n \subseteq \mathcal{Y}$ to conclude that (M, \mathcal{X}_n) is a β -model, and this is true for any \mathcal{Y} a β -(GB + ETR)-realization for M . \square

Theorem 33 (Main Theorem 4). *There is a minimum β -model of GB + ETR, if there is any β -model of GB + ETR. Moreover, this minimum β -model satisfies Global Choice.*

Proof. First, let us see that if M is β -(GB + ETR)-realizable then so is L^M . This is of independent interest, so I will separate it out as its own lemma.

Lemma 33.1. *If M is β -(GB + ETR)-realizable then L^M is β -(GBC + ETR)-realizable.*

Before proving this, let us see with an example why merely restricting the classes to those which are subclasses of L will not work. Suppose $(M, \mathcal{Y}) \models \text{GB} + \text{ETR}$ is transitive with $0^\sharp \in M$. Set $\mathcal{X} = \mathcal{Y} \cap \mathcal{P}(L^M)$. Then, (L^M, \mathcal{X}) fails to satisfy Replacement. Consider $A = 0^\sharp \cup (\text{Ord}^M \setminus \omega) \in \mathcal{X}$. But $A \cap \omega \notin L^M$, so (L^M, \mathcal{X}) fails to satisfy Replacement. That is, the problem is that \mathcal{Y} may contain subclasses of L^M which are not amenable to L^M .

Proof of lemma 33.1. Let $(M, \mathcal{Y}) \models \text{GB} + \text{ETR}$ be a β -model. Define $\mathcal{X} \subseteq \mathcal{Y}$ to consist of all the subsets of L^M which are amenable to L^M . That is, $X \in \mathcal{X}$ if and only if $X \subseteq L^M$ and $X \cap a \in L^M$ for all $a \in L^M$. By observation 21 we get that (L^M, \mathcal{X}) is a β -model. So the only work is to see that $(L^M, \mathcal{X}) \models \text{GBC} + \text{ETR}$. That it satisfies Extensionality and Global Choice is immediate. To see that it satisfies Class Replacement, take a class function $F \in \mathcal{X}$ and a set $a \in L^M$. Working in (M, \mathcal{Y}) , pick α so that $F \upharpoonright a \in V_\alpha^M$, which exists by Class Replacement in (M, \mathcal{Y}) . By amenability we now get that $f = F \cap (V_\alpha^M \cap L^M) \in L^M$. So $F''a = f''a \in L^M$, as desired.

To see that (L^M, \mathcal{X}) satisfies Elementary Comprehension, note that this follows immediately once we know that L^M satisfies Separation with parameters from \mathcal{X} , since $\{x : \varphi(x, \bar{P})\} \cap a = \{x \in a : \varphi(x, \bar{P})\}$. We check that Elementary Comprehension with parameters from \mathcal{X} holds by induction on formulae. The atomic and boolean cases are easy, but note that we use amenability to check the atomic case for the formula “ $x \in A$ ”. For the quantifier case, we want to see that $b = \{x \in a : \forall y \varphi^{L^M}(x, y)\} \in L^M$, where I have suppressed writing the parameters in φ . For each y , let $b_y = \{x \in a : \varphi^{L^M}(x, y)\}$, which is in L^M by inductive hypothesis. Then observe that $b = \{x \in a : \forall y x \in b_y\}$, so $b \in L^M$.

Finally, let us see that $(L^M, \mathcal{X}) \models \text{ETR}$. Consider a first-order formula $\varphi(x, Y, P)$ with the parameter $P \in \mathcal{X}$ and a class well-order $\Gamma \in \mathcal{X}$. By ETR in (M, \mathcal{Y}) there is a class $S \in \mathcal{Y}$ which satisfies $S_g = \{x : \varphi^{L^M}(x, S \upharpoonright x, P)\}$ for all $g \in \text{dom } \Gamma$. We inductively show that $S \in \mathcal{X}$. This induction can be carried out inside (M, \mathcal{Y}) because being amenable to L^M is an elementary property. The successor case follows because (L^M, \mathcal{X}) satisfies Elementary Comprehension. For the limit case, we consider $\Delta \subseteq \Gamma$ an initial segment without a maximum element and assume that $S \upharpoonright g \in \mathcal{X}$ for all $g \in \Delta$. We want to see that $S \upharpoonright \Delta \in \mathcal{X}$. Toward this end, fix $a \in L^M$. Now observe that

$$(S \upharpoonright \Delta) \cap a = \left(\bigcup_{g \in \text{dom } \Delta} S \upharpoonright g \right) \cap a = \{x \in a : \exists g \in \text{dom } \Delta x \in S \upharpoonright g\}.$$

Because being $S \upharpoonright g$ is an elementary property in the parameters Δ and g , and because we have that $S \upharpoonright g \in \mathcal{X}$ for all $g \in \text{dom } \Delta$, by Separation applied inside (L^M, \mathcal{X}) we thereby get that $(S \upharpoonright \Delta) \cap a \in L^M$. So $S \upharpoonright \Delta \in \mathcal{X}$, completing the argument. \square

Let L_α be so that α is the least ordinal with L_α being β -(GB + ETR)-realizable. By theorem 32, let \mathcal{X} be the minimum β -(GB + ETR)-realization for L_α . Note that (L_α, \mathcal{X}) satisfies Global Choice. I claim that (L_α, \mathcal{X}) is the desired minimum β -model of GB + ETR. To see this, there are two cases to consider. If $(M, \mathcal{Y}) \models \text{GB} + \text{ETR}$ is a β -model with $\text{Ord}^M = \alpha$, then theorem 32 yields that $\mathcal{X} \subseteq \mathcal{Y}$. For the other case, if $(M, \mathcal{Y}) \models \text{GB} + \text{ETR}$ with $\text{Ord}^M > \alpha$ then $L_\alpha \in M$ and thus M can construct \mathcal{X} by ordinary transfinite recursion on sets. Note that this uses that that the Γ used to build \mathcal{X} really are well-founded from the perspective of V , and hence also from the perspective of M . \square

Essentially the same argument gives minimum β -models for GB + ETR $_\Gamma$.

Lemma 34. *If $M \models \text{ZF}$ is β -(GB + ETR $_\Gamma$)-realizable for $\Gamma \in \mathcal{P}(M)$ with $\Gamma \geq \omega^\omega$ then M has a minimum β -(GB + ETR $_\Gamma$)-realization.*

The purpose of requiring $\Gamma \geq \omega^\omega$ is that this ensures ETR $_\Gamma$ is equivalent to the existence of Γ -iterated truth predicates relative to any class. See corollary 10. The same applies to later theorems, but I will suppress making this comment every time.

Proof of lemma 34. This is done almost the same as the proof for theorem 32. Namely, set $\mathcal{X}_0 = \text{Def}(M; \Gamma)$ and set \mathcal{X}_{n+1} to consist of all classes of M definable from $\text{Tr}_\Gamma(A)$ for $A \in \mathcal{X}_n$. Finally, set $\mathcal{X} = \bigcup_n \mathcal{X}_n$. These are well-defined because Γ is a well-order. Then, similar to before, (M, \mathcal{X}) is easily seen to be contained in any β -model $(M, \mathcal{Y}) \models \text{GB} + \text{ETR}_\Gamma$ and is itself a β -model of GB + ETR $_\Gamma$. \square

Theorem 35. *Let Γ be a name for a class well-order $\geq \omega^\omega$ which is absolute to L . That is, Γ is defined by some first-order formula without parameters so that any model of GB thinks the class defined by that formula is well-ordered and moreover $\Gamma^M = \Gamma^{L^M}$. (For instance, Γ might be Ord.) If there is a β -model of GB + ETR $_\Gamma$ then there is a minimum β -model of GB + ETR $_\Gamma$. And this minimum β -model moreover satisfies Global Choice.*

If there is to be a minimum β -model of GB + ETR $_\Gamma$ it must have a first-order part of the form L_α . The point of requiring Γ to be absolute to L is to exclude uninteresting counterexamples like “ $\Gamma = \text{Ord}$ if $V = L$ and $\Gamma = \omega^\omega$ otherwise”. And Γ should be definable by a first-order formula so that different GB-realizations for the same M agree on what Γ is.

Proof. This follows from lemma 34 plus the fact that if M is β -(GB + ETR $_\Gamma$)-realizable then so is L^M . This fact can be proved similar to the argument for lemma 33.1. The difference is that rather than needing to consider recursions along any well-founded relation, we only consider recursions along well-founded relations of rank $\leq \Gamma$. \square

We get minimum transitive models for ETR $_{\text{Ord}}$ and other sufficiently weak fragments of ETR.

Lemma 36. *If transitive $M \models \text{ZF}$ is (GB + ETR $_{\text{Ord}}$)-realizable then M has a minimum (GB + ETR $_{\text{Ord}}$)-realization. If M has a definable global well-order then this minimum (GB + ETR $_{\text{Ord}}$)-realization moreover satisfies Global Choice.*

Proof. For the proof of lemma 34 the only place it was used that M is β -(GB + ETR $_\Gamma$)-realizable was to get that Γ really is well-founded (i.e. in V). But the Ord of a transitive model of GB is well-founded, even if it fails to be a β -model. So the exact same argument goes through. That is, the minimum (GB + ETR $_{\text{Ord}}$)-realization for M is $\mathcal{X} = \bigcup_n \mathcal{X}_n$ where $\mathcal{X}_0 = \text{Def}(M)$ and $\mathcal{X}_{n+1} = \bigcup \{\text{Def}(M; \text{Tr}_{\text{Ord}}(A)) : A \in \mathcal{X}_n\}$. \square

Theorem 37. *If there is a transitive model of $\text{GB} + \text{ETR}_{\text{Ord}}$ then there is a minimum transitive model of $\text{GB} + \text{ETR}_{\text{Ord}}$. And this minimum model satisfies Global Choice.*

Proof. Combine lemma 36 plus the fact that M being $(\text{GB} + \text{ETR}_{\text{Ord}})$ -realizable implies L^M is $(\text{GB} + \text{ETR}_{\text{Ord}})$ -realizable. Again, this is proved much the same as lemma 33.1, except looking only at recursions along well-founded relations of rank $\leq \text{Ord}$. \square

The attentive reader will notice that the above argument applies to more than just Ord . Specifically, the only fact about Ord that was used was that if M is transitive then Ord^M is well-founded. The same argument goes through if Ord is replaced by a name for an ordinal or a class well-order which is well-founded in any transitive model. So the same argument goes through more generally, for example if Ord is replaced by ω_1 or Ord^{Ord} or $\text{Ord}^{\text{Ord}^{\text{Ord}}} + \text{Ord}^{\text{Ord}} + \text{Ord}$ or many other names for well-orders.

Left open by this analysis is how far we can go. There are names Γ for class well-orders so that there are transitive (M, \mathcal{X}) with $\Gamma^{(M, \mathcal{X})}$ ill-founded (i.e. in V). In particular, this holds if Γ is defined as the least class well-order so that L_Γ is admissible. But that definition of Γ requires quantifying over classes. What if we only allow definitions that are first-order?

Question 38. *If Γ is a name for a class well-order defined by a first-order formula, must it be the case that Γ^M is well-founded (in the ambient universe) for any transitive $M \models \text{ZF}$?*

To finish this section, let us see that ETR is not equivalent to ETR_Γ for any Γ . Moreover, we can separate fragments of ETR . This establishes that theorem 35 is not redundant with theorem 33 and that theorem 37 does not immediately imply that there is a minimum transitive model of ETR .

First, if Γ is sufficiently smaller than Δ then a model of ETR_Γ need not be a model of ETR_Δ .

Theorem 39. *Let $(M, \mathcal{X}) \models \text{GB}$ and let $\Gamma \in \mathcal{X}$ be a well-order $\geq \omega^\omega$. Suppose that $(M, \mathcal{X}) \models \text{ETR}_{\Gamma \cdot \omega}$. Then, there is $\mathcal{Y} \subseteq \mathcal{X}$ coded in \mathcal{X} so that $(M, \mathcal{Y}) \models \text{GB} + \text{ETR}_\Gamma$ but $(M, \mathcal{Y}) \not\models \text{ETR}_{\Gamma \cdot \omega}$. If (M, \mathcal{X}) moreover satisfies Global Choice, then \mathcal{Y} can be picked so that (M, \mathcal{Y}) also satisfies Global Choice.*

Proof. Define

$$\mathcal{Y} = \{X \in \mathcal{X} : X \in \text{Def}(M; \text{Tr}_\Xi), \text{ where } \Xi \text{ is some initial segment of } \Gamma \cdot \omega^M\}.$$

Then, \mathcal{Y} is coded in \mathcal{X} via the code $C = \{(g, \varphi, a), x) : (g, \varphi, a \hat{\ } x) \in \text{Tr}_{\Gamma \cdot \omega}\}$. Also, \mathcal{Y} is the increasing union of the $\text{Def}(M; \text{Tr}_\Xi)$ for Ξ initial segments of $\Gamma \cdot \omega$, each of which is a GB -realization for M . Thus, $(M, \mathcal{Y}) \models \text{GB}$. Next, (M, \mathcal{Y}) satisfies Elementary Transfinite Recursion for recursions of rank $\leq \Gamma$ because given $X \in \mathcal{Y}$ it must be that $X \in \text{Def}(M; \text{Tr}_\Xi)$ for some Ξ an initial segment of $\Gamma \cdot \omega$ and thus $\text{Tr}_\Gamma(X) \in \text{Def}(M; \text{Tr}_{\Xi + \Gamma(X)}) \subseteq \mathcal{Y}$. Finally, $(M, \mathcal{Y}) \not\models \text{ETR}_{\Gamma \cdot \omega}$ because it does not contain $\text{Tr}_{\Gamma \cdot \omega}$.

To prove the fact about Global Choice, do the same construction but look at iterated truth predicates relative to a fixed global well-order. \square

This result is optimal for transitive models because ETR_Γ is equivalent to $\text{ETR}_{\Gamma \cdot n}$ for any standard $n \in \omega$.²⁶

²⁶For ω -nonstandard models ETR_Γ is not equivalent to $\text{ETR}_{<\Gamma \cdot \omega}$. Suppose $(M, \mathcal{X}) \models \text{ETR}_{\Gamma \cdot \omega}$ and let $I \subseteq \omega^M$ be an initial segment closed under addition. A similar construction can be used to get $\mathcal{Y} \subseteq \mathcal{X}$ so that (M, \mathcal{Y}) satisfies $\text{ETR}_{\Gamma \cdot n}$ if and only if $n \in I$.

By near the same argument one can separate ETR_Γ from $\text{ETR}_{<\Gamma}$, for Γ satisfying a basic closure condition.

Corollary 40. *Let $(M, \mathcal{X}) \models \text{GB}$ and let $\Gamma \in \mathcal{X}$ be a well-order $\geq \omega^\omega$ so that Γ is closed under addition. That is, if $\Delta < \Gamma$ is a well-order then $\Delta + \Delta < \Gamma$. Then, if $(M, \mathcal{X}) \models \text{ETR}_\Gamma$ there is $\mathcal{Y} \subseteq \mathcal{X}$ coded in \mathcal{X} so that $(M, \mathcal{Y}) \models \text{GB} + \text{ETR}_{<\Gamma}$ but $(M, \mathcal{Y}) \not\models \text{ETR}_\Gamma$. If (M, \mathcal{X}) moreover satisfies Global Choice then \mathcal{Y} may be fixed so that (M, \mathcal{Y}) also satisfies global choice. \square*

As an immediate corollary we get that fragments of ETR can be separated by consistency strength.

Corollary 41. *Let Γ be a name for a well-order $\geq \omega^\omega$, given by a first-order formula without parameters. Then $\text{GB} + \text{ETR}$ proves $\text{Con}(\text{GB} + \text{ETR}_\Gamma)$. Moreover if Γ and Δ are names for well-orders given by first-order formulae without parameters, then GB proves $\Gamma \cdot \omega \leq \Delta$ implies that $\text{GB} + \text{ETR}_\Delta$ proves $\text{Con}(\text{GB} + \text{ETR}_\Gamma)$.*

Proof. Let $(M, \mathcal{X}) \models \text{GB} + \text{ETR}_\Delta$. By the previous theorem there is $\mathcal{Y} \subseteq \mathcal{X}$ coded in \mathcal{X} so that $(M, \mathcal{Y}) \models \text{GB} + \text{ETR}_\Gamma$. But (M, \mathcal{X}) has access to the full second-order truth predicate for coded models, via an elementary recursion of length ω . So $(M, \mathcal{X}) \models \text{Con}(\text{GB} + \text{ETR}_\Gamma)$. \square

One can similarly state and prove a separation of $\text{ETR}_{<\Gamma}$ and ETR_Γ by consistency strength. I leave this to the reader.

In theorem 39 we produced a model (M, \mathcal{Y}) of $\text{GB} + \text{ETR}_\Gamma$ which was not a model of $\text{GB} + \text{ETR}_{\Gamma \cdot \omega}$. But this was due to a deficiency the second-order part. We produced \mathcal{Y} by taking a restricted collection of classes from \mathcal{X} so as to not have long enough iterated truth predicates to get a model of $\text{ETR}_{\Gamma \cdot \omega}$. Can we separate fragments of ETR with the first-order part of a model? That is, is there $M \models \text{ZFC}$ so that M is $(\text{GB} + \text{ETR}_\Gamma)$ -realizable but not $(\text{GB} + \text{ETR}_{\Gamma \cdot \omega})$ -realizable?

Of course, if we put no restriction on M then this follows immediately from the fact that $\text{GB} + \text{ETR}_{\Gamma \cdot \omega}$ proves the consistency of $\text{GB} + \text{ETR}_\Gamma$. If M is the first-order part of a model of $\text{GB} + \text{ETR}_\Gamma + \neg \text{Con}(\text{GB} + \text{ETR}_{\Gamma \cdot \omega})$ then M will not be $(\text{GB} + \text{ETR}_{\Gamma \cdot \omega})$ -realizable. Such M will necessarily be ω -nonstandard. Can we make the same separation, but with an M which is ω -standard, or even transitive?

The answer is yes, looking below ETR_{Ord} .

Theorem 42. *Suppose γ is a name for an ordinal $\geq \omega^\omega$ given by a first-order formula without parameters. (In particular, γ is a set, not a proper class.) If there is a transitive model of $\text{GB} + \text{ETR}_{\gamma \cdot \omega}$ then there is transitive M which is $(\text{GB} + \text{ETR}_\gamma)$ -realizable but not $(\text{GB} + \text{ETR}_{\gamma \cdot \omega})$ -realizable.*

Proof. Take $(N, \mathcal{Y}) \models \text{GB} + \text{ETR}_{\gamma \cdot \omega}$ which has a first-order definable global well-order. Consider the iterated truth predicates $\vec{T} = \{\text{Tr}_\xi : \xi = \gamma \cdot n\}$ and let $(M; \vec{S}) = \text{Sk}^{(N, \vec{T})}(\gamma)$ be the Skolem hull of γ in the structure $(N; \vec{T})$. By elementarity, $\vec{S} = \{(\text{Tr}_\xi)^M : \xi = \gamma \cdot n\}$. Moreover, $\gamma \cdot n \in N$ for all n because $(N; \vec{T})$ satisfies that the length of each truth predicate in \vec{T} is a set.

Let $\mathcal{X} = \text{Def}(M; \vec{S})$. Then, $(M, \mathcal{X}) \models \text{ETR}_\gamma$; given $A \in \mathcal{X}$ there is n so that A is definable from $\text{Tr}_{\gamma \cdot n}(\vec{G})$. But then $\text{Tr}_\gamma(A)$ is definable from $\text{Tr}_{\gamma \cdot (n+1)}$.

However, M is not $(\text{GB} + \text{ETR}_{\gamma \cdot \omega})$ -realizable. This is because the $(\gamma \cdot \omega + 1)$ -iterated truth predicate for M reveals that M is a Skolem hull and hence countable. But no model of ZFC thinks that it is countable. So no GB -realization for M can contain $\text{Tr}_{\gamma \cdot \omega + 1}^M$, which $\text{GB} + \text{ETR}_{\gamma \cdot \omega}$ proves exists. \square

The proof that there is a minimum β -model of $\text{GB} + \text{ETR}$ came down to two facts: first, that if a model of ZFC with a definable global well-order is β -($\text{GB} + \text{ETR}$)-realizable then it has a minimum β -($\text{GB} + \text{ETR}$)-realization; second, that if M is β -($\text{GB} + \text{ETR}$)-realizable then so is L^M . One strategy to try to prove the existence of a minimum transitive model of $\text{GB} + \text{ETR}$ would be to prove analogues of these two facts. The latter—i.e. that if M is ($\text{GB} + \text{ETR}$)-realizable then so is L^M —can be proven by an argument similar to the proof of lemma 33.1.

I do not see how to settle the analogue of the first fact. Working towards a positive answer, the proof of theorem 33 does not generalize to show that transitive ($\text{GB} + \text{ETR}$)-realizable models have minimum ($\text{GB} + \text{ETR}$)-realizations. Working towards a negative answer, the argument in the next section that no countable model of ZFC has a minimum KM-realization does not generalize down to $\text{GB} + \text{ETR}$. The trouble is that $\text{GB} + \text{ETR}$ is too weak for the same proof to go through. Namely, $\text{GB} + \text{ETR}$ does not prove that $\text{Hyp}(V)$ exists; cf. lemma 50.1.

Question 43. *If M is ($\text{GB} + \text{ETR}$)-realizable, must M have a minimum ($\text{GB} + \text{ETR}$)-realization? What if we restrict to the case where M is transitive?*

A positive answer to this question would imply a positive answer to the following, the main open question from this article.

Question 44. *Is there a minimum transitive model of $\text{GB} + \text{ETR}$?*

I have a partial answer.

Theorem ([Wil18, theorem 4.40]). *Suppose $M \models \text{ZF}$ is ($\text{GB} + \text{ETR}$)-realizable. Then M has minimal ($\text{GB} + \text{ETR}$)-realizations. Further, if \mathcal{X} is any ($\text{GB} + \text{ETR}$)-realization for M then \mathcal{X} contains precisely one of these minimal realizations. Even further, if \mathcal{X} and \mathcal{Y} are amalgamable ($\text{GB} + \text{ETR}$)-realizations, meaning there is a GB -realization $\mathcal{Z} \supseteq \mathcal{X}, \mathcal{Y}$ for M , then \mathcal{X} and \mathcal{Y} contain the same minimal realization.²⁷*

6. KM AND OTHER STRONG THEORIES

Before presenting the results about models of KM, let me review for the benefit of the reader some facts from the study of admissible sets. Kripke–Platek set theory KP is the (first-order) set theory consisting of the axioms of Extensionality, Pairing, and Union, along with the Σ_0 -Separation, Σ_0 -Collection, and Π_1 -Foundation²⁸ schemata. It will be convenient in this context to go beyond pure sets and consider *urelements*, objects which are not sets but can be members of sets. KPU is the variation of KP formulated in a context allowing urelements; see [Bar75, Chapter I.2] for a precise axiomatization. Transitive models of KPU are known as *admissible sets*. I will write $\mathfrak{A} = (A, U; R_0, \dots)$ for the admissible set A with U as its set of urelements, \in for its membership relation, and additional relations, constants, or functions R_0, \dots . Given a structure $(U; R_0, \dots)$, where we may assume U consists of urelements, there is a smallest admissible set $\mathfrak{A} = (A, U; R_0, \dots)$ with $U \in A$. This smallest admissible set containing U is denoted $\text{Hyp}(U)$. If U is a well-founded model of set theory without urelements then U will be isomorphic to a pure transitive set in $\text{Hyp}(U)$, where a set is pure if it has no urelements in its transitive closure. If we call this transitive set \bar{U} , then the pure sets of $\text{Hyp}(U)$ are precisely $L_\alpha(\bar{U})$, where α is the least ordinal so that $L_\alpha(\bar{U}) \models \text{KP}$. And from $L_\alpha(\bar{U})$ we can recover U thought of as a set of urelements and all of $\text{Hyp}(U)$. When

²⁷The version of this theorem in my dissertation is stated for M satisfying AC, but it is straightforward to see that this extra assumption is not used.

²⁸Recall that Γ -Foundation asserts that every nonempty class definable from a formula in Γ has an \in -minimal element.

working with U a transitive model of set theory I will tacitly identify $\text{Hyp}(U)$, the model with urelements, with $L_\alpha(\bar{U})$, the model with only pure sets.

There is a tight connection between admissible sets and infinitary logics. Countable admissible sets capture fragments of $\mathcal{L}_{\omega_1, \omega}$ which admit a form of compactness. Let \mathfrak{A} be a countable admissible set. Then $\mathcal{L}_{\mathfrak{A}}$ is the infinitary fragment of $\mathcal{L}_{\infty, \omega}$ associated with \mathfrak{A} . Namely, formulae in $\mathcal{L}_{\mathfrak{A}}$ may only have finite quantifier blocks but allow disjunctions and conjunctions over Φ a set of formulae so that $\Phi \in \mathfrak{A}$. Barwise proved that these admissible fragments of $\mathcal{L}_{\omega_1, \omega}$ satisfy a form of compactness: if an $\mathcal{L}_{\mathfrak{A}}$ theory $T \subseteq A$ is Σ_1 definable over \mathfrak{A} then T has a model if and only if every $T_0 \subseteq T$ in \mathfrak{A} has a model.

I will make use of the following result about admissible sets, due also to Barwise. First, let me fix some notation. Consider the structure $\mathfrak{A} = (A, U; E, \dots)$ where U consists of urelements, A consists of sets, and E is a binary relation. For $a \in A$ set $a_E = \{x \in \mathfrak{A} : x E a\}$. Say that $S \subseteq U$ is *internal* for \mathfrak{A} if there is $a \in A$ so that $S = a_E$.

Theorem 45 (Barwise [Bar75, Theorem IV.1.1]). *Let $(U; R_0, \dots)$ be a countable structure and let $\mathfrak{A} = \text{Hyp}(U)$. Suppose T is an $\mathcal{L}_{\mathfrak{A}}$ theory which is Σ_1 -definable over \mathfrak{A} and has a model of the form $\mathfrak{B} = (B, U; E, R_0, \dots)$. Suppose $S \subseteq U$ is internal for every such \mathfrak{B} . Then $S \in \text{Hyp}(U)$.*

This result is an infinitary version of a well-known theorem due to Gandy, Kreisel, and Tait, with $\text{Hyp}(U)$ being the higher-order analogue to the collection of hyperarithmetic sets.

Theorem (Gandy–Kreisel–Tait [GKT60]). *Let T be a Π_1^1 -definable set of axioms for second-order arithmetic, where T extends $\Sigma_1^1\text{-AC}_0$. If $S \subseteq \omega$ is internal to every model of T , then S is hyperarithmetic.*

The admissible preliminaries out of the way, let us begin with Marek and Mostowski's theorem that there is a smallest β -model of KM. I include a proof for the sake of completeness of presentation.

Theorem 46 (Marek–Mostowski [MM75]). *There is a minimum β -model of KM, if there is any β -model of KM. Moreover, this minimum model also satisfies Global Choice and Class Choice.*

Proof. Suppose there is a β -model of KM. By theorem 18 there is a β -model of $\text{KMC} + \text{Class Collection}$. Its unrolling is a well-founded model of ZFC_1^- .²⁹ So there is a transitive model of ZFC_1^- . Let L_α be the minimum transitive model of ZFC_1^- .³⁰ Let $\kappa < \alpha$ be the largest cardinal in L_α . Set $(M, \mathcal{X}) = (L_\kappa, \mathcal{P}(L_\kappa) \cap L_\alpha)$. I claim that (M, \mathcal{X}) is the minimum β -model of KM. First, observe that it is itself a β -model since L_α is correct about well-foundedness.

Take $(N, \bar{\mathcal{Y}})$ a β -model of KM. By theorem 18 there is $\mathcal{Y} \subseteq \bar{\mathcal{Y}}$ so that $(L^N, \mathcal{Y}) \models \text{KMC} + \text{Class Collection}$. Now let $W \models \text{ZFC}_1^-$ be the unrolling of (N, \mathcal{Y}) . Because (N, \mathcal{Y}) is a β -model, W must be well-founded. Identify W with its transitive collapse. Then, $L_\alpha \subseteq W$, because L_α is the minimum transitive model of ZFC_1^- .

Let λ be the largest cardinal in W . There are two cases. The first is if $\lambda > \kappa$. Then, because W thinks λ is inaccessible, W thinks $\mathcal{P}(L_\kappa)$ exists. Therefore, $\mathcal{X} = \mathcal{P}(L_\kappa) \cap L_\alpha \in V_\lambda^W = N$. The second case is if $\lambda = \kappa$. Then, $\text{Ord}^W \geq \alpha$ by the minimality of L_α . Thus, $\mathcal{X} = \mathcal{P}(L_\kappa) \cap L_\alpha \subseteq \mathcal{P}(L_\kappa) \cap W$ so $\mathcal{X} \subseteq \bar{\mathcal{Y}}$. In either case, we then conclude that $M \subseteq N$ and $\mathcal{X} \subseteq \bar{\mathcal{Y}}$. \square

Essentially the same argument gives the existence of minimum β -KM-realizations.

²⁹Recall definition 17.

³⁰To see such exists: Take $M \models \text{ZFC}_1^-$ transitive with $\kappa \in M$ the largest cardinal. Then κ is inaccessible in L^M so $L_{(\kappa^+)L^M} \models \text{ZFC}_1^-$. So the minimum transitive model of ZFC_1^- is L_α for α least such that there is a transitive model of ZFC_1^- of height α .

Theorem 47 (Marek and Mostowski [MM75]). *Suppose $M \models \text{ZF}$ is β -KM-realizable. Then M has a minimum β -KM-realization. In particular, in this case $(M, \mathcal{X}_{\beta, \text{KM}}) \models \text{KM}$.³¹ \square*

Ratajczyk improved their methods to apply to weaker theories.

Theorem 48 (Ratajczyk [Rat79]). *Let $k \geq 1$. There is a minimum β -model of $\text{GB} + \Pi_k^1\text{-CA}$, if there is any β -model of $\text{GB} + \Pi_k^1\text{-CA}$. Moreover, this minimum model also satisfies Global Choice and Class Choice. And if $M \models \text{ZF}$ is β - $(\text{GB} + \Pi_k^1\text{-CA})$ -realizable then M has a minimum β - $(\text{GB} + \Pi_k^1\text{-CA})$ -realization.*

The analogous result fails if we look at transitive models, rather than confining ourselves to β -models.

Theorem 49 (Main Theorem 3). *There is not a minimum transitive model of KM. Moreover, for any real r there is not a minimum transitive model of KM which contains r . Indeed, the same holds if KM is replaced by any T extending $\text{GB} + \Pi_1^1\text{-CA}$ with the property that T is an element of any transitive model of T . In particular, this holds for any computably axiomatizable extension of $\text{GB} + \Pi_1^1\text{-CA}$.*

The original proof I found for this went through Barwise's notion of the *admissible cover*. Ali Enayat privately communicated to me an alternative argument which goes through the above theorem of Barwise. With his kind permission it is his proof I present here.³²

The key fact to establish this theorem is encapsulated by the following lemma.

Lemma 50 (Key Lemma; Ali Enayat). *Suppose $M \models \text{ZF}$ is countable. Let $T \subseteq \omega$ be a second-order set theory extending $\text{GB} + \Delta_1^1\text{-CA}$ with one of the following properties, depending on whether M is ω -standard. If M is ω -standard, then $T \in M$; or if M is ω -nonstandard, then there is $t \in \mathcal{P}(\omega)^M$ so that T is the standard part of t . Suppose M is T -realizable. Then*

$$\mathcal{X}_T(M) = \bigcap \{ \mathcal{X} \subseteq \mathcal{P}(M) : (M, \mathcal{X}) \models T \} = \text{Hyp}(M) \cap \mathcal{P}(M).$$

Proof. (\subseteq) We want to consider two-sorted models of the form $\mathfrak{B} = (B, M; E)$. This argument now breaks into cases depending upon whether M is ω -standard. First work in the case where M is ω -standard. Consider the following $\mathcal{L}_{\text{Hyp}(M)}$ -theory \bar{T} which can hold of such a two-sorted model. Namely, \bar{T} asserts that M and C make up, respectively, the sets and classes of a model of T , using the membership relation E so that $E \upharpoonright M$ is \in^M . It is immediate that $(B, M; E) \models \bar{T}$. Note M is definable by a single $\mathcal{L}_{\text{Hyp}(M)}$ sentence, and so we get that \bar{T} really can express that the first-order part of the model is M . Similarly, we can express as a single $\mathcal{L}_{\text{Hyp}(M)}$ assertion that $E \upharpoonright M$ is \in^M . Combined with the assumption that $T \in M$ we get that $\bar{T} \in \text{Hyp}(M)$, and in particular is Σ_1 -definable over $\text{Hyp}(M)$. Observe that any $(M, \mathcal{X}) \models T$ gives rise to $\mathfrak{B} \models \bar{T}$ in the obvious manner. So if $S \subseteq M$ is an element of every T -realization for M then S is internal for every $\mathfrak{B} \models \bar{T}$. So by Barwise's theorem 45 we get that $S \in \text{Hyp}(M)$.

Now let us consider the case when M is ω -nonstandard. In this case, we want \bar{T} to be the $\mathcal{L}_{\text{Hyp}(M)}$ -theory asserting that M and C make up, respectively, the sets and classes of a model of the standard part of t , using the membership relation E so that $E \upharpoonright M$ is \in^M . Again, as a single $\mathcal{L}_{\text{Hyp}(M)}$ -sentence we can express that the first-order part really is M and that $E \upharpoonright M$ is \in^M . So to see that $\bar{T} \in \text{Hyp}(M)$, and thus that \bar{T} really is a $\mathcal{L}_{\text{Hyp}(M)}$ -theory, we only have to see that

³¹Recall definition 6.

³²The reader who wishes to see the admissible cover argument can find it in my dissertation [Wil18], written while the current article was under review.

the standard part of t is in $\text{Hyp}(M)$. First, observe that since $\text{Hyp}(M)$ has an infinite set as an element, namely M itself, $\text{Hyp}(M)$ must contain ω as an element. Therefore, $\text{Hyp}(M)$ can see the unique embedding of ω onto an initial segment of ω^M . From this embedding $\text{Hyp}(M)$ can extract the standard part of any $x \in M$ so that $M \models x \subseteq \omega^M$. The rest of the argument is now the same: If $S \subseteq M$ is an element of every T -realization for M then S is internal for every $\mathfrak{B} \models \bar{T}$ and so by Barwise's theorem 45 we get that $S \in \text{Hyp}(M)$.

(\supseteq) This argument is the same whether or not M is ω -standard. Take $S \in \text{Hyp}(M) \cap \mathcal{P}(M)$. Then S is Δ_1^1 over M without class parameters, but possibly allowing parameters from M ; see [Bar75, corollary IV.3.4]. Observe that Σ_1^1 definitions (without class parameters) over M are upward absolute. That is, for $a \in M$ and $\mathcal{X} \subseteq \mathcal{P}(M)$, if $\varphi(x)$ is Σ_1^1 then $(M, \mathcal{X}) \models \varphi(a)$ implies $(M, \mathcal{P}(M)) \models \varphi(a)$. This is because any witness in \mathcal{X} to $\varphi(a)$ must also be in $\mathcal{P}(M)$. And dually, Π_1^1 definitions (without class parameters) over M are downward absolute; if $\varphi(x)$ is Π_1^1 then $(M, \mathcal{P}(M)) \models \varphi(a)$ implies $(M, \mathcal{X}) \models \varphi(a)$. Let \mathcal{X} be any T -realization for M . Then, combining the absoluteness facts with the fact that T includes Δ_1^1 -Comprehension we get that $S \in \mathcal{X}$, completing the argument. \square

Proof of theorem 49 (Ali Enayat). Fix a real r . If T has no transitive model containing r , then the conclusion is trivially satisfied. So assume we are in the case where there is a transitive model of T containing r . Suppose toward a contradiction that (M, \mathcal{X}) is the minimum transitive model of T which contains r . By a Löwenheim–Skolem argument it must be that M is countable. So by the key lemma we get that $\mathcal{X} = \text{Hyp}(M) \cap \mathcal{P}(M)$. Let us see that this is in fact impossible, giving the desired contradiction.

Recall from the discussion at the end of section 2 that T is strong enough to carry out the unrolling construction, working with membership codes for ‘sets’ of rank $> \text{Ord}$. As I remarked, the unrolling and cutting off constructions are inverses. Applied to this case, we get that cutting off $\text{Hyp}(M)$ to get (M, \mathcal{X}) and then unrolling produces an isomorphic copy of $\text{Hyp}(M)$. In particular, we get that (M, \mathcal{X}) unrolls to $\text{Hyp}(M)$.

In that earlier discussion we were interested in the structure obtained by looking at all of these membership codes, but here we are also interested in properties of individual membership codes. Specifically, given a membership code which represents a transitive set³³ we can ask which set theoretic axioms it satisfies. We can sensibly formulate this, since given the truth predicate $\text{Tr}(E)$ we can extract a truth predicate for the transitive set coded by E . More specifically, we can ask whether E represents a transitive model of KP. And we can also ask whether the canonical membership code representing M is a member of E . That is, we can query whether there is $a E m_E$ so that E restricted to below a is isomorphic to \in^M . In summary, we can ask whether there is coded in \mathcal{X} an admissible set which contains M as an element.

Let “ $\text{Hyp}(V)$ exists” be the statement in second-order set theory asserting that there is a membership code for a transitive model of KP which contains the class of all sets as an element. If there is any such membership code, there there is a minimum up to isomorphism such membership code. This is then the membership code for $\text{Hyp}(V)$.

Lemma 50.1. $\text{GB} + \Pi_1^1\text{-CA}$ proves that $\text{Hyp}(V)$ exists.

This lemma can also be found as [ABF, theorem 64]. Antos, Barton, and Friedman also show that the classes coded as elements of $\text{Hyp}(V)$ form a model of $\text{GB} + \Delta_1^1\text{-CA}$, whence they conclude

³³To be clear, E is a membership code for a transitive set if $a E b E m_E$, where m_E is the maximum element of E , implies $a E m_E$.

that $\text{GB} + \Delta_1^1\text{-CA}$ does not prove that $\text{Hyp}(V)$ exists. One can check that this model also satisfies ETR , and so $\text{GB} + \Delta_1^1\text{-CA} + \text{ETR}$ does not prove that $\text{Hyp}(V)$ exists. For the benefit of the reader, I provide a proof of this result here from the assumption of KM . The reader who wants a proof from the weaker theory should consult Antos, Barton, and Friedman, or see my dissertation [Wil18, lemma 4.24].

Proof from KM. By theorem 18 we may assume Class Collection without loss. Now work in the unrolling, which satisfies ZF_1^- . Let κ denote the largest cardinal in the unrolled structure, so that V_κ in the unrolling is the V of the ground model. Note that ZF^- proves the reflection schema relative to the $L(A)$ hierarchy for any A . That is, for each formula $\varphi(x, a)$ with a parameter a , ZF^- proves that there are cofinally many ordinals α so that for all $x \in L_\alpha(A)$ we have $L_\alpha(A) \models \varphi(x, a)$ if and only if $\varphi(x, a)^{L(A)}$. This is proved via the usual argument, but using the $L(A)$ hierarchy instead of the V hierarchy. Since ZF^- includes KP and “ $N \models \text{KP}$ ” can be expressed as a single formula in the language of set theory, we get that in the unrolling there is an ordinal $\alpha > \text{Ord}^M$ so that $L_\alpha(V_\kappa) \models \text{KP}$. Thus, in the ground model satisfying $\text{KM} + \text{Class Collection}$ we get that there is a membership code for a transitive model of KP which contains the class of all sets as an element. \square

By this lemma, there is a membership code which (M, \mathcal{X}) thinks represents $\text{Hyp}(M)$ inside $\mathcal{X} = \text{Hyp}(M) \cap \mathcal{P}(M)$. Thus, if we unroll \mathcal{X} to get $\text{Hyp}(M)$ then we find that there is $A \in \text{Hyp}(M)$ which is a transitive model of KP with $M \in A$. This contradicts that $\text{Hyp}(M)$ is the minimum such transitive model of KP . Therefore, our original assumption that (M, \mathcal{X}) is the minimum transitive model of T must be wrong. So T does not have a minimum transitive model. \square

Note that we actually proved the following stronger result.

Corollary 51. *Let $M \models \text{ZF}$ be countable and transitive and suppose $T \in M$ is an extension of $\text{GB} + \Pi_1^1\text{-CA}$. Then M does not have a minimum T -realization.*

Proof. Suppose towards a contradiction that \mathcal{X} is the minimum T -realization for M . By lemma 50, it must be that $\mathcal{X} = \text{Hyp}(M) \cap \mathcal{P}(M)$. But because T proves $\text{Hyp}(V)$ exists we get $A \in \text{Hyp}(M)$ which is an admissible set containing M as an element, a contradiction. \square

This result also holds in case M is not transitive. (But note that if M is ω -nonstandard then instead of asking that $T \in M$ we have to ask that T is the standard part of an M -real $t \in \mathcal{P}(\omega)^M$.) See [Wil18, corollary 4.26].

A natural next question is to weaken minimum to minimal, and ask whether there are minimal transitive models of KM . This is answered by the following theorem.³⁴

Theorem 52. *Let $M \models \text{ZF}$ be countable. Then M has a minimal KM -realization if and only if M has a β - KM -realization.*

Proof. (\Leftarrow) By theorem 47 if M has a β - KM -realization it must have a minimum β - KM -realization. Then by observation 21 this minimum β - KM -realization must be a minimal KM -realization for M .

(\Rightarrow) This direction goes through a theorem due to Quinsey.

Theorem (Quinsey [Qui80, corollary 6.7]). *Fix $n \in \omega$ and let $W \models \text{ZF}^-$ be countable and non-standard. Then there is $U \models \text{ZF}^-$ so that $U \prec_{\Sigma_n} W$ is strictly end-extended by W .*

³⁴I thank the referee for pointing out to me the forward direction of the argument for this theorem.

The argument goes by the contrapositive. Suppose that M has no β -KM-realization. If M is not KM-realizable at all, then the conclusion is trivial. For the substantive case, suppose $(M, \mathcal{X}) \models \text{KM}$. If \mathcal{X} were uncountable, then by the downward Löwenheim–Skolem theorem it could not be a minimal KM-realization for M . In the case where \mathcal{X} is countable, let $W \models \text{ZF}_I^-$ be the unrolling of (M, \mathcal{X}) . Then W is nonstandard, as (M, \mathcal{X}) is wrong about well-foundedness. Because being the largest cardinal of a model of ZF^- is a definable property, Quinsey’s theorem gives us $U \models \text{ZF}_I^-$ which is strictly end-extended by W so that U and W agree on V_κ , with κ the largest cardinal of the model. Thus, $(M, \mathcal{Y}) = (V_\kappa^U, V_{\kappa+1}^U) \models \text{KM}$ is a strict submodel of (M, \mathcal{X}) . Therefore, \mathcal{X} is not a minimal KM-realization for M , as desired. \square

Corollary 53. *There is no minimal transitive model of KM. That is, if $(M, \mathcal{X}) \models \text{KM}$ then there is $(N, \mathcal{Y}) \models \text{KM}$ a strict submodel of (M, \mathcal{X}) .*

Proof. If (M, \mathcal{X}) were to be a minimal transitive model of KM, then \mathcal{X} would have to be a minimal KM-realization for M . In such a case, by the previous theorem it must be that (M, \mathcal{X}) is a β -model. Now apply Marek and Mostowski’s result [MM75, theorem 3.2] that every β -model of KM contains a transitive model of KM as a set. This then gives that there is $(N, \mathcal{Y}) \in M$ a transitive model of KM, witnessing that (M, \mathcal{X}) cannot be a minimal transitive model of KM. \square
